## **Erklärung**

I hereby declare that this Ph.D. thesis is the result of my own work carried out between the winter semester of 2008 and the winter semester of 2012 in the group of Prof. Dr. Bernd Mueller-Roeber at the University of Potsdam in Golm, Germany. It has not been submitted for any degree or Ph.D. at any other university.

Magda Ewa Lotkowska

Potsdam, 15.05.2013

### **Acknowledgements**

First and foremost, I would like to express my gratitude to Prof. Dr. Bernd Mueller-Roeber for his excellent supervision. He guided me wisely throughout my Ph.D. project, at the same time giving me enough freedom to develop and pursue my own scientific interests. His advice, encouragement and support were invaluable and helped me to complete my work successfully.

I am grateful to Dr. Katrin Czempinski, for brilliant organisation of the VaTEP project; a great adventure that gave me the opportunity to meet researchers from all over the world and take part in many conferences and workshops.

To Dr. Ina Talke - the coordinator of the IMPRS-PMPG doctoral programme, which gave me the possibility to interact more closely with Ph.D. students and researchers of the Max Planck Institute (MPI).

I would like to thank all current and former members of the Mü-Rö group, for their help, advice and friendship. My special thanks goes to Dr. Salma Balazadeh for sharing her excellent knowledge and expertise in working with transcription factors, and for revealing the secrets of chromatin immunoprecipitation. Big thanks to Dr. Luiz Gustavo Guedes Correa, Dr. Samuel Arvidsson, Dr. Pawel Gajdanowicz and Dr. Tripti Sharma for stimulating discussions and creating a nice environment to work in. To Mamoona and Arif, Nooshin and Amin, Lilian, Sara, Anu and Prashanth for their useful comments and suggestions; to Fernando, Diego, Flavia, Zina, Mathias, Ola, Kamil, Radek and Julia for providing a vibrant and cheerful atmosphere both inside and outside the lab; to Dagmar, Eike, Antje and Karina for taking care of the laboratory equipment and enzymes, for autoclaving media and solutions.

I would like to express my huge gratitude to Ines Nowak for excellent care in her administrative work and for her kindness.

I also would like to acknowledge our collaborators; Prof. Alisdair Fernie and Dr. Takayuki Tohge (MPI) for metabolite profiling experiments, and Dr. Gang-Ping Xue (CSIRO Plant Industry, Australia) for binding site selection experiments.

Thanks to the greenhouse personnel both at the University of Potsdam - Christiane Schmid and Doreen Mäker and at the MPI - especially Karin Köhl and Linda Bartetzko, for their help with plant transformations and maintenance.

## *Acknowledgements*

---

I would like to thank Dr. Eugenia Maximova for providing help with microscopy, Dr. Armin Schlereth for help with quantitative RT-PCR and Josef Bergstein for the excellent photography.

Thanks to the EU-funded project VaTEP ('Vacuolar transport equipment for growth regulation in plants', MRTN-CT-2006-035833) for the funding during the first three years of my Ph.D. studies.

Last, but certainly not least, I would like to thank my family, especially my dear parents Iwona and Andrzej, and my brother Krzysztof, who are always there for me. I am also grateful to my wonderful husband Julal, for his love, encouragement and support in my daily endeavours. The final acknowledgement goes to someone very special, someone whose heart has been beating inside of me for the past seven months, for his playful kicks and pushes, during the writing of this thesis.

Thanks to all, who I may have forgotten to mention in this Acknowledgements.

### 1. Summary

Transcription factors (TFs) are ubiquitous gene expression regulators and play essential roles in almost all biological processes. This Ph.D. project is primarily focused on the functional characterisation of *MYB112* - a member of the R2R3-MYB TF family from the model plant *Arabidopsis thaliana*. This gene was selected due to its increased expression during senescence based on previous qRT-PCR expression profiling experiments of 1880 TFs in *Arabidopsis* leaves at three developmental stages (15 mm leaf, 30 mm leaf and 20% yellowing leaf). *MYB112* promoter GUS fusion lines were generated to further investigate the expression pattern of *MYB112*. Employing transgenic approaches in combination with metabolomics and transcriptomics we demonstrate that *MYB112* exerts a major role in regulation of plant flavonoid metabolism. We report enhanced and impaired anthocyanin accumulation in *MYB112* overexpressors and *MYB112*-deficient mutants, respectively. Expression profiling reveals that *MYB112* acts as a positive regulator of the transcription factor *PAP1* leading to increased anthocyanin biosynthesis, and as a negative regulator of *MYB12* and *MYB111*, which both control flavonol biosynthesis. We also identify *MYB112* early responsive genes using a combination of several approaches. These include gene expression profiling (Affymetrix ATH1 micro-arrays and qRT-PCR) and transactivation assays in leaf mesophyll cell protoplasts. We show that *MYB112* binds to an 8-bp DNA fragment containing the core sequence (A/T/G)(A/C)CC(A/T)(A/G/T)(A/C)(T/C). By electrophoretic mobility shift assay (EMSA) and chromatin immunoprecipitation coupled to qPCR (ChIP-qPCR) we demonstrate that *MYB112* binds *in vitro* and *in vivo* to *MYB7* and *MYB32* promoters revealing them as direct downstream target genes. MYB TFs were previously reported to play an important role in controlling flavonoid biosynthesis in plants. Many factors acting upstream of the anthocyanin biosynthesis pathway show enhanced expression levels during nitrogen limitation, or elevated sucrose content. In addition to the mentioned conditions, other environmental parameters including salinity or high light stress may trigger anthocyanin accumulation. In contrast to several other MYB TFs affecting anthocyanin biosynthesis pathway genes, *MYB112* expression is not controlled by nitrogen limitation, or carbon excess, but rather is stimulated by salinity and high light stress. Thus, *MYB112* constitutes a previously uncharacterised regulatory factor that modifies anthocyanin accumulation under conditions of abiotic stress.

## 2. General Introduction

### 2.1. Transcription Factors

Transcription is the first step leading to gene expression. It is the process of synthesising a complementary RNA strand from a DNA template. In eukaryotes, transcription is mediated by multi-protein complexes. These include the basal transcriptional apparatus composed of general transcription factors (GTFs) and the RNA polymerase complex, multi-subunit cofactors, as well as chromatin remodelling and DNA unwinding factors (Sekine *et al.*, 2012; Levine and Tjian, 2003; Riechmann, 2002; **Figure 1**). Selectivity of transcription is provided by the action of sequence-specific transcription factors (TFs). TFs are typically composed of a DNA binding domain (DBD) and an effector/regulatory domain responsible for activator or repressor activity. These factors recognise specific DNA motifs, usually located in the promoters of target genes, and regulate the frequency of transcription initiation.

**Figure 1. The multi-subunit general transcription apparatus.**

The eukaryotic transcriptional apparatus can be subdivided into three broad classes of multi-subunit ensembles that include the RNA polymerase II (RNAPII) core complex and associated general transcription factors (GTFs: IIA, -B, -D, -E, -F and -H), multi-subunit co-activator and mediator proteins and various chromatin modifying or remodelling complexes.

This is achieved through direct or indirect (through transcriptional regulators) interaction between the effector domain of a TF and the basal transcriptional apparatus. The DNA motifs, or *cis*-regulatory elements bound by TFs usually compose of 5 - 10 nucleotides and can often be recognised by a set of different TFs, acting synergistically or as competitors. Properties of TFs open the possibility for precise control over temporal and spatial patterns of gene transcription despite a limited number of factors and binding sites. On the basis of similarities in the DBD sequence, TFs were classified into different families, some widespread among eukaryotes, other exclusive for a particular kingdom (Riechmann *et al.*, 2000).

### 2.1.1. Transcription Factors in Plants

The genome of the model plant *Arabidopsis thaliana* is estimated to encode over 2400 TF and transcriptional regulator genes, which accounts for around 7.5% of the predicted total number of genes (Pérez-Rodríguez *et al.*, 2009). In *Populus trichocarpa*, TFs account for 6.3% and in *Vitis vinifera* - 5.7% of all genes, whereas in *Drosophila melanogaster*, *Caenorhabditis elegans* and *Saccharomyces cerevisiae* the proportions are 4.6%, 3.5% and 3.5%, respectively (Riechmann *et al.*, 2000; PInTFDB; Pérez-Rodríguez *et al.*, 2010). The higher number of TFs in plants can be attributed to the complex secondary metabolism (Szathmáry *et al.*, 2001), interactions with environment necessitated by the sessile lifestyle of plants and due to extensive genome duplications (Riechman, 2001). The *Arabidopsis thaliana* TF genes have been classified into 60 families and 22 gene families encoding for other transcriptional regulators (Pérez-Rodríguez *et al.*, 2010). The two largest TF families are the MYB superfamily (197 members in *Arabidopsis*; Katiyar *et al.*, 2012) and the APETALA2/ethylene responsive element binding protein (AP2/EREBP) (147 members; Pérez-Rodríguez *et al.*, 2010; Zhang *et al.*, 2012).

### 2.1.2. MYB Superfamily of Transcription Factors

MYB domain TFs are present in all eukaryotic organisms and are thought to be over one billion years old (Lipsick, 1996). The *MYB* acronym is derived from

"myeloblastosis", a type of leukaemia (cancer of blood cells) and the first *MYB* gene identified was the oncogene *v-Myb* derived from the avian myeloblastosis virus (AMV). This retrovirus causes monoclastic leukemia in chickens and possibly may have originated by the insertion of a retrovirus into a proto-oncogene (*c-Myb*), which mutated and became a part of the virus (Klempnauer and Bishop, 1983). The MYB domain generally consists of up to three imperfect repeats (R1, R2 and R3) composed of 50-53 amino acids each, but four-repeat exceptions exist (Wong *et al.*, 1998; **Figure 2**). There is greater conservation between the same repeat from different proteins than between R2 and R3 repeats from the same protein suggesting that each repeat has a specialized function in binding DNA. R2 and R3 domains in *c-MYB* are required for binding to the DNA although it has been proposed that R3 is involved in more specific interactions with the nucleotides of the binding motif than R2 (Ogata *et al.*, 1992). In animals, the MYB superfamily is relatively small, generally comprising only four or five proteins, usually containing three MYB repeats (R1, R2 and R3). Animal MYB factors are responsible for the regulation of cell proliferation, differentiation and apoptosis. In plants, R1R2R3-MYB factors are rare (five members in *Arabidopsis*). The plant DBD usually consists of two imperfect repeats (R2, R3) and out of 1976 MYB proteins, there are 126 members of the R2-R3 group in *Arabidopsis*. There are also several single repeat (MYB-related) factors found in *Arabidopsis* e.g. MYBL2, CPC and TRY (Matsui *et al.*, 2008; Simon *et al.*, 2007; Tominaga *et al.*, 2007). Structural studies showed that imperfect repeats of the MYB domain fold into helix-loop-helix motifs separated by highly conserved tryptophan residues, that stabilise the hydrophobic core of the MYB domain (Kaneishi *et al.*, 1990). The MYB domain is generally found in the N-terminus of the protein, however can be also present in the C-termini. Usually however, the regulatory domain is located in the C-terminal part of the protein. Within their regulatory domains, members of the MYB family contain serine and threonine residues, indicating possible post-translational regulation of MYB activity by phosphorylation. For instance, the MYB-related TF *MYB340* from *Antirrhinum* when synthesized in *E. coli* or in yeast, shows little DNA binding affinity and recovers after treatment of extracts with alkaline phosphatase. This indicates that the DNA binding activity of this TF is inhibited by phosphorylation (Moyano *et al.*, 1996). MYB proteins can also interact with other TFs. Such interactions are common for *c-MYB*. Also plant

MYB factors interact with partner proteins, such as those from the bHLH TF family. In *Zea mays*, the transcriptional activation of anthocyanin biosynthesis genes by the R2R3 MYB proteins C1 and P1 requires the involvement of bHLH proteins from the R/B gene family (Goff *et al.*, 1992). Analysis of protein-protein interactions of the MYB family in the model plant *Arabidopsis thaliana* revealed a conserved amino acid sequence ([DE]Lx2[RK]x3Lx6Lx3R) as the structural basis for interaction between MYB and R/B-like bHLH proteins (Zimmerman *et al.*, 2010).

**Figure 2. General structure of MYB proteins.**

The MYB DNA-binding domain generally consists of up to three imperfect repeats (R1, R2 and R3) composed of 50-53 amino acids and is located in the N-terminus of the protein. The regulatory domain is present in the C-terminus of the protein and contains interaction sites for partner proteins (stars), i.e. a conserved amino acid sequence ([DE]Lx2[RK]x3Lx6Lx3R) as the structural basis for interaction between MYB and R/B-like bHLH proteins.

### 2.1.2.1. R2R3-MYB Factors

MYB factors were substantially amplified in plants, as compared to animals and yeast, and they comprise one of the largest TF families with at least 197 members in *Arabidopsis* and 155 in rice (Katiyar *et al.*, 2012). The majority of MYB TFs in plants contain two imperfect repeats of the MYB domain and there are 126 R2R3-MYBs in *Arabidopsis* and 109 R2R3-MYBs in rice. Contrary to genes encoding R1R2R3-MYB proteins, *R2R3-MYB* genes are not the equivalents of c-MYB from animals and are unique to plants. While plant R1R2R3-MYB proteins play similar functions to their animal counterparts, *R2R3-MYB* genes mainly regulate plant-specific processes. A systematic analysis of knockouts has revealed that R2R3-MYB factors play roles

## 2. General Introduction

mainly in the regulation of secondary metabolism, plant cell shape and plant organ development (Stracke *et al.*, 2001; Jin and Martin, 1999; Meissner *et al.*, 1999, Martin and Paz-Ares, 1997). On the basis of similarities in the C-terminal amino acid sequence, R2R3 factors were classified to 22 subgroups in *Arabidopsis* (Kranz *et al.*, 1998). The conserved motifs may facilitate protein functionality outside of the DNA-binding domain and closely related members of the same subgroup often exhibit similar functions. **Figure 3** shows the integrated evolutionary relationships of the 126 *Arabidopsis* R2R3-MYB proteins with their depicted functions.

**Figure 3. Integrated evolutionary relationships of the 126 *Arabidopsis* R2R3-MYB proteins with indicated functions (Matus *et al.*, 2008, modified).**

It has been shown for example that factors from subgroup 7 (i.e., MYB11/PFG2, MYB12/PFG1 and MYB111/PFG3) control the flavonol biosynthesis pathway and factors from subgroup 6 (i.e., MYB75/PAP1, MYB90/PAP2, MYB113 and MYB114)

regulate expression of anthocyanin biosynthesis genes. Interestingly, the *MYB114* gene from the Columbia (Col) accession encodes a putative protein that lacks a transcriptional activation domain due to a stop codon just after the MYB domains (at amino acid 140). The Landsberg erecta (Ler) *MYB114* allele encodes a full-length gene and its function in anthocyanin accumulation was confirmed (Gonzalez *et al.*, 2008). Another prominent example represents the three factors which build subgroup 15, i.e. Glabrous 1 (GL1/MYB0), Werewolf (WER/MYB66) and MYB23 (Kranz *et al.*, 1998; Stracke *et al.*, 2001). WER/MYB66 and GL1/MYB0 are functionally equivalent proteins (Lee and Schiefelbein, 2001) and display their different biological functions in root hair and trichome formation, respectively, only because of their different spatial expression patterns (reviewed in Schiefelbein, 2003). Moreover, MYB23 is redundant to GL1/MYB0 in controlling the initiation of trichome development (Kirik *et al.*, 2001). Regulators of Axillary Meristems RAX1/MYB37, RAX2/MYB38, and RAX3/MYB84 belong to subgroup 14 (Muller *et al.*, 2006) and are homologous to the tomato (*Solanum lycopersicum*) *BLIND* gene (Schmitz *et al.*, 2002) controlling the formation of lateral meristems in different, but overlapping zones along the shoot axis.

### 2.1.3. MYB112 is an R2R3-MYB from Subgroup 20

Phylogenetic analysis of MYB factors in *Arabidopsis* places MYB112 in subgroup 20 of the R2R3-MYB group (Stracke *et al.*, 2001). Apart from MYB112, there are five other MYB proteins found in this subgroup: MYB2, MYB62, MYB78, MYB108 and MYB116 (**Figure 4**). The functions of MYB2, MYB62 and MYB108 were previously described. MYB108 contributes to the regulation of stamen maturation and male fertility in response to jasmonate signaling (Mandaokar and Browse, 2009). MYB62 regulates phosphate starvation responses and gibberellic acid biosynthesis (Devaiah *et al.*, 2009). The MYB2 protein has been shown to be a transcriptional activator of the *DEHYDRATION RESPONSIVE GENE (rd22)* (Abe *et al.*, 2003) and to act in abscisic acid signaling. Guo and Gan (2011) reported that MYB2 regulates whole-plant senescence by inhibiting cytokinin-mediated branching at late stages of development in *Arabidopsis*.

**Figure 4. Phylogenetic relationship of transcription factors in subgroup 20 of the R2R3-MYB group** (Stracke *et al.*, 2001).

The function of MYB112 has not yet been described. A literature search revealed, however, that expression of *MYB112* increases during leaf aging. According to the eFP browser (Winter *et al.*, 2007), when considering the array data from developmental series, *MYB112* expression reaches its maximum value during leaf senescence (**Figure 5A**), which is in accordance with data extracted from Genevestigator (<http://www.genevestigator.com>, Zimmermann *et al.*, 2004a). This also stays in agreement with the results published by Balazadeh *et al.* (2008), when screening for genes showing altered expression in leaves during late stages of development, comprising 50% of leaf full expansion (15 mm), fully expanded leaf (30 mm) and 20% senescent leaf (determined as yellowing of 20% of the leaf blade) with the use of quantitative reverse transcription-polymerase chain reaction (qRT-PCR). The final stage (20% yellowing) is a leaf in which photoassimilates and nutrients are intensively remobilized and transported to other organs of the plant. In this study, a significant increase of *MYB112* expression level was observed in the yellowing leaf (Balazadeh *et al.*, 2008) (**Figure 5B**). Breeze *et al.* (2011) performed microarray-based high-resolution gene expression profiling using samples collected over 11 time points during a 3-week period leading to leaf senescence. They observed that the major switch in gene expression, both in genes up- and down-regulated, occurred

## 2. General Introduction

between 29 and 33 days after sawing (DAS). Expression of *MYB112* increased rapidly after at 31 DAS and reached its maximum at 33 DAS (**Figure 5C**).

**Figure 5. *MYB112* expression profiling during leaf development.**

**(A)** Representation of microarray-based *MYB112* expression profiling during leaf development according to eFP browser (Winter *et al.*, 2007). **(B)** Expression of *MYB112* in leaves at three developmental stages as measured by qRT-PCR (based on Balazadeh *et al.*, 2008). **(C)** Expression of *MYB112* measured using microarrays at 11 stages of 3-week time to leaf senescence as described by Breeze *et al.* (2011). Note the increase of *MYB112* expression during senescence.

The functional analysis of genes up-regulated after 31 DAS illustrates the degradation and mobilization of nutrients, with 44% of these genes involved in catalytic activity, with lipid catabolism highly represented, and 10% having a role in transport (Breeze *et al.*, 2011). According to microarray data (Genevestigator) expression of *MYB112* increases also upon a range of stresses, such as pathogen attack, drought, osmotic stress and salt stress. Interestingly, salt stress can cause premature senescence and expression of many TFs involved in the regulation of senescence processes (senescence-associated TFs, SAGs) increases also during salt stress (reported by Balazadeh *et al.*, 2010).

## 2.2. Flavonoids

### 2.2.1. Flavonoid Biosynthesis

Flavonoids are a major class of plant secondary metabolites, composed of a fifteen-carbon skeleton, which consists of two phenyl rings (A- and B-rings) connected by a three-carbon bridge (C-ring) (**Figure 6**). The skeleton can be modified by numerous additional hydroxyl, methoxyl, methyl and/or glycosyl substitutions, giving rise to various compounds. Additionally, aromatic and aliphatic acids, sulfate, prenyl or methylenedioxy groups also attach to the flavonoid skeleton (Harborne and Baxter, 1999). Depending on their chemical structure, flavonoids are divided into several groups, i.e., anthocyanins, flavonols, flavones, flavanones, dihydroflavonols, isoflavonoids, chalcones, aurones, condensed tannins (or proanthocyanidins), and others (Iwashina, 2000). Flavonoids are synthesised by the phenylpropanoid pathway. Studies in *Arabidopsis thaliana* largely contributed to our understanding of the phenylpropanoid pathway, its enzymes and intermediates. The molecular basis of the flavonoid biosynthesis pathway is well known in plants (for reviews see Koes *et al.*, 2005; Falcone Ferreyra *et al.*, 2012), and metabolic engineering of flavonoid biosynthesis is actively pursued (Butelli *et al.*, 2008; Tanaka *et al.*, 2010; Wang *et al.*, 2011). In this pathway the amino acid phenylalanine is used to produce 4-coumaroyl-CoA, which reacts with malonyl-CoA leading to production of the fifteen-carbon chalcones. The first reaction, in which phenylalanine undergoes deamination to

## 2. General Introduction

yield *trans*-cinnamic acid and ammonia is catalysed by Phenylalanine Ammonia-Lyase (PAL) (**Figure 7**). In *Arabidopsis*, there are four genes encoding PAL isoforms: *PAL1-PAL4* (Raes *et al.*, 2003). Kinetic analysis of PAL activity *in vitro* as well as studies using reverse genetics revealed that *PAL1* and *PAL2* encode the major functional PAL enzymes in *Arabidopsis*, while *PAL4* partially compensates for the loss of *PAL1* and *PAL2*. (Cochrane *et al.*, 2004; Rohde *et al.*, 2004; Huang *et al.*, 2010 ). The following hydroxylation of cinnamate to yield 4-coumarate (also known as *p*-coumaric acid) is catalysed by Cinnamate-4-Hydroxylase (C4H). C4H is a cytochrome P450-dependent monooxygenase and mutation its gene causes reduced epidermal fluorescence and a decreased accumulation of sinapoylmalate and condensed tannins (Ruegger and Chapple, 2001; Schilmiller *et al.*, 2009). The metabolic changes are accompanied by developmental, structural, and reproductive phenotypes, i.e., dwarfism, reduced apical dominance, collapsed xylem, male sterility. 4-Coumarate:CoA Ligase (4CL) catalyzes the ATP-dependent formation of the CoA thioester 4-coumaroyl CoA (also known as *p*-coumaroyl CoA; **Figure 7**).

**Figure 6. Structure of the flavonoid backbone.**

Fifteen-carbon flavonoid skeleton consists of two phenyl rings (A- and B-rings) connected by a three-carbon bridge (C-ring)

The *Arabidopsis* genome encodes at least four such proteins: 4CL1-4CL4 (Ehltling *et al.*, 1999; Hamberger and Hahlbrock, 2004; Costa *et al.*, 2005). Based on their expression patterns and their similarity to 4CL homologues found in other plants, 4CL1 and 4CL2 are proposed to be involved in lignin biosynthesis, while 4CL3 may have a role in flavonoid biosynthesis (Ehltling *et al.*, 1999; Cukovic *et al.*, 2001). 4CL4 exhibits preferential activity not towards *p*-coumarate but towards ferulate and sinapate, suggesting a metabolic function different from the other three isozymes (Hamberger and Hahlbrock, 2004). The first step in flavonoid biosynthesis is catalysed by Chalcone Synthase (CHS). The resulting chalcone scaffold is

subsequently modified by the action of Chalcone Isomerase (CHI) and Flavanone-3-Hydroxylase (F3H) to yield dihydroflavonols (**Figure 7**). Dihydroxyflavonols give rise to either flavonols, i. e., quercetin and kaempferol, or anthocyanins. Flavonol Synthase (FLS) catalyses the production of flavonols, whereas Dihydroflavonol-4-Reductase (DFR) is the first enzyme of the anthocyanin branch of the flavonoid pathway. Anthocyanin aglycones are synthesised by Anthocyanidin Synthase (ANS, LDOX) and undergo extensive modifications by glycosyltransferases (AGTs), acyltransferases (ACTs) and glutathione-S-transferases (GSTs) before transport to the vacuole. Similarly, quercetin and kaempferol undergo modifications to glycosylated varieties.

### 2.2.2. Regulation of Flavonoid Biosynthesis by R2R3-MYB Factors

Understanding the role of flavonoids in plant development and stress response is intimately linked to understand how the expression of the biosynthetic pathway genes is controlled. The precise regulation of flavonoid production is achieved by the combinatorial action of transcription factors (TFs), expressed in a spatially and temporally controlled manner (reviewed in Koes *et al.*, 2005; Lepiniec *et al.*, 2006). TFs regulating the expression of flavonoid biosynthesis genes have been characterized quite extensively in *Arabidopsis* and other plant species including petunia (*Petunia hybrid*), maize (*Zea mays*) and snapdragon (*Antirrhinum majus*) (Broun, 2005; Ramsay and Glover, 2005; Allan *et al.*, 2008; Hichri *et al.*, 2011; Petroni and Tonelli, 2011). Regulators belonging to different TF families, including WD40, WRKY, BZIP, MADS-box, bHLH and MYB proteins, have been proven to control expression of flavonoid biosynthesis genes (reviewed in Ramsay and Glover, 2005). The first plant TF reported to be involved in the regulation of the flavonoid pathway was the MYB factor Colorless1 (C1) isolated from *Zea mays* in 1987 (Paz-Ares *et al.*, 1987). C1 interacts with bHLH factors B and R to activate the promoter of *DIHYDROFLAVONOL-4-REDUCTASE* (DFR) (Chandler *et al.*, 1989; Ludwig *et al.*, 1989; Goff *et al.*, 1992, Mol *et al.*, 1996). The specificity of this interaction was confirmed by comparing C1 with a closely related P protein - a MYB TF which controls a set of flavonoid biosynthesis genes independent of bHLH TFs (Grotewold *et al.*, 1994). The regulation of the flavonoid pathway dependent on MYB and bHLH

## 2. General Introduction

---

partnership is conserved throughout the plant kingdom, i. e., the *Petunia hybrida* MYB protein Anthocyanin2 (AN2) interacts with the bHLH proteins JAF13 and AN1, the *Antirrhinum* MYBs Ros1, Ros2 and VeMut interact with Del bHLHs, and MYB1 from strawberry is able to interact with the maize bHLH protein R (Quattrocchio *et al.*, 1999; Aharoni *et al.*, 2001). In *Arabidopsis*, four anthocyanin-regulating MYBs have been identified, including Production of Anthocyanin Pigment 1 (PAP1/MYB75), including Production of Anthocyanin Pigment 2 (PAP2/MYB90), MYB113 and MYB114. These TFs belong to subgroup 6 of the R2R3-MYB family and interact with bHLH factors, including Glabra 3 (GL3/bHLH001), Enhancer of Glabra 3 (EGL3/bHLH002) and TT8/bHLH042 (Zhang *et al.*, 2003; Baudry *et al.*, 2006; Gonzalez *et al.*, 2008). The regulatory complex also includes the WD40 protein Transparent Testa Glabra 1 (TTG1), a homolog of AN11 from *Petunia hybrida*, which also controls anthocyanin production (de Vetten *et al.*, 1997; Walker *et al.*, 1999). The resulting MYB/bHLH/WD40 (MBW) complex binds to the *DFR* promoter and induces its expression. The seed-specific R2R3-MYB factor Transparent Testa 2 (TT2/MYB123) also requires interaction with a bHLH factor, i.e., TT8, to activate the target genes *DFR*, *BANYULS* (*BAN*) and the *MULTIDRAG AND TOXIC COMPOUND EXTRUSION (MATE)*-type transporter *TT12*. Seeds of *transparent testa* mutants are yellow or pale-brown in colour because they fail to produce proanthocyanidins in the testa (seed coat) (Koornneef, 1990; Shirley *et al.*, 1995; Nesi *et al.*, 2001). The *Arabidopsis* Production of Flavonol Glycoside factors from the R2R3-MYB subgroup 7, namely PFG1/MYB12, PFG2/MYB11 and PFG3/MYB111, have been found to control the flavonol branch of the flavonoid biosynthesis pathway by activating *CHALCONE SYNTHASE (CHS)*, *CHALCONE ISOMERASE (CHI)*, *FLAVANONE-3-HYDROXYLASE (F3H)* and *FLAVONOL SYNTHASE (FLS)* in a bHLH-independent manner (Mehrtens *et al.*, 2005; Stracke *et al.*, 2007, Stracke *et al.*, 2010). Analysis of protein-protein interactions of the MYB family in the model plant *Arabidopsis thaliana* revealed a conserved amino acid sequence ([DE]Lx2[RK]x3Lx6Lx3R) as the structural basis for the interaction between MYB and bHLH proteins (Zimmerman *et al.*, 2010). A number of RR3-MYBs were reported to act as negative regulators. For example, MYB4 from *Arabidopsis* was reported to act as a negative regulator of *CHS*, *4CL1* and *4CL3* genes (Zimmerman *et al.*, 2004),

and the *myb4* knockout mutant showed an increase in sinapate ester accumulation, which resulted in enhanced UV-B irradiation tolerance (Jin *et al.*, 2000)..

**Figure 7. Flavonoid biosynthesis pathway.**

Flavonoids are synthesised from phenylalanine in the phenylpropanoid pathway. The first step in flavonoid biosynthesis is catalysed by chalcone synthase (CHS). Flavonol biosynthesis branch of the pathway is indicated with a blue box. Expression of genes encoding flavonol biosynthesis enzymes is directly regulated by MYB11, MYB12 and

MYB111, PAP1, PAP2, MYB113, and MYB114 control the expression of anthocyanin biosynthesis genes (red box).

Overexpression of *MYB1* from strawberry in tobacco resulted in suppression of anthocyanin and flavonol accumulation (Aharoni *et al.*, 2001). Recently, transient suppression of *MYB1* gene was shown to cause increased accumulation of anthocyanins in strawberry fruits (Salvatierra *et al.*, 2013). Jin *et al.* (2000) identified a conserved repression motif (pdLNLD/ELxiG/S) in the C-terminal regions of these MYB proteins.

To summarise, branches of flavonoid metabolism are regulated by interplay between branch-specific activating and repressing MYB TFs, some of which depend on specific bHLH or WD40 protein partners. However, it remains unclear how the TF activity itself is regulated by internal or external signals to pursue controlled responses and what regulates these regulators.

### 2.2.3. Anthocyanins – the Colourful Flavonoids

Flavonoids are a diverse class of secondary metabolites, proven to play a remarkable role in the interaction between plants and their environment, often critical for plant survival. These compounds are crucial for the symbiotic plant-microbe interactions and in plant sexual reproduction by promoting the pollen tube development (Koes *et al.*, 1994). They also have apparent roles in plant stress defence, such as in protection against damage caused by wounding, pathogen attack, osmotic stress, salinity, extreme temperatures and excessive light (Dixon and Paiva, 1995; Winkel-Shirley, 2002). Anthocyanins are a small group of flavonoid pigments. In plant reproductive organs, anthocyanins act as pollinator attractants. The production of anthocyanins in plant foliage has long been the subject of study and speculation (early references reviewed by Wheldale, 1916; Dooner *et al.*, 1991; Mol *et al.*, 1996). Over the years numerous hypotheses have been proposed to account for the presence of anthocyanins in leaves of a wide range of species. In the late 19th century several authors suggested the light screen hypothesis, which states that foliar anthocyanins protect the photosynthetic apparatus from excess light (reviewed

by Wheldale, 1916). When leaves receive more light energy than can be used in photochemistry, they show a decline in the quantum efficiency of photosynthesis, termed photoinhibition (Long *et al.*, 1994). Under severe conditions chloroplasts generate reactive oxygen species (ROS), which have the potential to destroy thylakoid membranes and denature proteins associated with photosynthetic electron transport. Therefore, the development of mechanisms that protect the photosynthetic apparatus under challenging conditions has been an essential component of higher plant evolution. *In vivo*, anthocyanins absorb the green and yellow wavelengths of light, commonly between 500 and 600 nm (Neill and Gould, 1999; Gitelson *et al.*, 2001) and therefore serve as a useful optical filter, diverting excess high-energy quanta away from the photosynthetic apparatus. Chloroplasts irradiated with light that has first passed through a red filter have been shown to generate fewer superoxide radicals, resulting in reduced structural damage to the photosystems (Neill and Gould, 2003). In addition, anthocyanins have been shown to be excellent scavengers of free radicals, suggesting dual photoprotective role of these compounds (Rice-Evans *et al.*, 1997; Wang *et al.*, 1997; Gould *et al.*, 2002; Nagata *et al.*, 2003). It has been shown that under stress conditions, e.g., high light, drought, salt stress and nutrient deficiencies (Heldt 1997; Dauborn and Brueggemann, 1998) as well as during senescence (Kar *et al.* 1993; Hoch *et al.*; 2003; Wingler *et al.* 2004), the probability of photoinhibition increases and even moderate irradiances can induce photoinhibitory damage. The close relationship between the appearance of anthocyanins in senescing leaves of wild-type plants and the development of photoinhibition in anthocyanin-deficient mutants of three woody species investigated by Hoch *et al.* (2003) suggests the need for the additional photoprotection provided by anthocyanins. The light screen hypothesis was later extended to formulate the resorption protection hypothesis, proposing that shielding photosynthetic tissues from excess light by anthocyanins allows the resorption of critical foliar nutrients during foliar senescence (Hoch *et al.*, 2001). Anthocyanins protect the degrading chlorophyll from damaging light levels, thereby restricting the formation of ROS that could jeopardize the resorptive process. Consistent with this hypothesis, nitrogen resorption has been shown to be more efficient in wild-type than in anthocyanin-deficient mutants of woody species (Feild *et al.*, 2001, Hoch *et al.*, 2001 and 2003, Lee, 2003).

### 2.3. Aim of the Thesis

Plant genome research is a major focus in our group and we study molecular and physiological processes that control plant development and responses to abiotic stress. We are particularly interested in the functional analysis of transcription factors and the regulatory networks they control. We explore such networks in *Arabidopsis thaliana* and other model plants. The aim of this thesis was to unravel the function of a previously uncharacterised gene encoding an R2R3-MYB factor - *MYB112*, as well as the MYB112-controlled gene expression network, including the identification of the early responsive and direct target genes. Systematic analysis of mutant plants with impaired expression of R2R3-MYB proteins in *Arabidopsis* as well as in other species resulted in rapid increase in our understanding of their function in plants. R2R3-MYB factors were reported to play roles mainly in the regulation of secondary metabolism, plant cell shape and plant organ development. *MYB112* was selected due to its elevated expression during senescence based on previous qRT-PCR expression profiling of 1880 TFs in *Arabidopsis* leaves at three developmental stages (15 mm leaf, 30 mm leaf and 20% yellow leaf). The main goal of this work was to investigate the function of the MYB112 transcription factor through the integration of metabolomics and transcriptomics, and to unravel MYB112 gene expression network using available *in vitro* and *in vivo* approaches.

## 3. Results

### 3.1. Molecular Characterisation of *MYB112* Transgenic Plants

The *MYB112* gene consists of three exons and encodes a protein of 243 amino acids. In order to investigate the function of *MYB112 in planta* we analysed two *myb112* mutants with the T-DNA insertion localised to the 5'-UTR (*myb112-1*; GK093E05) or 3'-UTR (*myb112-2*; Salk098029) of the gene (**Figure 8A**). Decreased level of functional, full-length *MYB112* transcript in homozygous mutants was confirmed using PCR (**Figure 8B**). This measurement revealed that down-regulation of *MYB112* expression was more pronounced in case of line *myb112-1* than in the *myb112-2* line. *MYB112* RNAi lines were obtained from AGRIKOLA (<http://www.agrikola.org>) and *MYB112* transcript level was analysed in seven selected lines (**Figure 8C**). The strongest decrease in *MYB112* expression, around 32-fold compared to wild type, was observed for lines RNAi#2 and RNAi#10. These lines were used for further analysis of growth phenotypes.

Transgenic plants expressing *MYB112* under the control of both, a synthetic estradiol (EST)-inducible promoter (*MYB112-IOE*) and the constitutive Cauliflower Mosaic Virus (CaMV) 35S promoter (*35S:MYB112* and *MYB112-GFP*) were generated in the *Arabidopsis* Col-0 background. *MYB112-IOE* plants were obtained by cloning of the *MYB112* coding sequence into the pER8 vector (Zuo *et al.*, 2000). After selection on antibiotic containing MS media, two-week old *MYB112-IOE* seedlings were transferred to liquid MS media and expression of *MYB112* was induced by addition of 10  $\mu$ M estradiol. After two hours of induction plants were harvested and the *MYB112* transcript level was measured using qRT-PCR. We could detect around 5-fold increase of *MYB112* expression in the estradiol-treated plants in comparison to DMSO-treated control plants (**Figure 9A**). We have also tested the expression level of *MYB112* in selection-surviving *35S:MYB112* and *MYB112-GFP* lines. Measurements were performed using two-week-old seedlings grown *in vitro* on MS media (**Figure 9B** and **9C**). We could observe an up to 5- and 15-fold increase in *MYB112* expression in *35S:MYB112-GFP#4* and *35S:MYB112#3* lines, respectively. These lines were selected for further studies.

**Figure 8. Molecular characterisation of *myb112* T-DNA insertion mutants and *MYB112* RNAi lines.**

(A) Location of T-DNA insertion in the two *myb112* T-DNA insertion mutants. (B) Decreased level of *MYB112* transcript in *myb112-1* and *myb112-2* mutant plants, shown by semi-quantitative RT-PCR (26 cycles) with primers annealing to the start and stop regions of the coding segment. (C) *MYB112* expression level in empty vector (EV) and RNAi plants determined using qRT-PCR. The data is represented as  $40-\Delta C_t$ , where  $\Delta C_t$  is equal to  $C_t$  gene of interest -  $C_t$  reference gene *UBQ10*. Data are means of three independent experiments  $\pm$  SD.

**Figure 9. Molecular characterisation of *MYB112* overexpression plants.**

Comparison of *MYB112* expression in selected lines of *MYB112* overexpression plants measured in two-week-old *Arabidopsis* seedlings using qRT-PCR. **(A)** *MYB112-IOE* seedlings treated for 2 h with 10  $\mu$ M estradiol in liquid MS medium, supplemented with 1% sucrose. As controls, DMSO-treated *MYB112-IOE* plants were used. Average log<sub>2</sub> values  $\pm$  SD measured by qRT-PCR are shown. **(B)** 35S:*MYB112* and wild-type seedlings. **(C)** 35S:*MYB112-GFP* and wild-type seedlings. The data are represented as 40- $\Delta C_t$ , where  $\Delta C_t$  is equal to  $C_{t\_gene\_of\_interest} - C_{t\_reference\_gene\_Actin}$ . Data are means of three independent experiments  $\pm$  SD. Asterisks indicate statistically significant differences to wild type as determined by Student's *t*-test,  $p < 0.05$  **(B-C)**.

### 3.2. Subcellular Localisation and Spatio-temporal Expression Pattern of MYB112

#### a. Subcellular Localisation of MYB112

To test the subcellular localisation of MYB112 protein we expressed it as a fusion to the N-terminus of green fluorescent protein (GFP) using the Cauliflower Mosaic Virus 35S (CaMV) promoter. The *35S:MYB112-GFP* construct was transformed into *Arabidopsis* plants and transgenic lines were selected on antibiotic-containing MS medium. Increased expression of *MYB112* was confirmed for three out of four *35S:MYB112-GFP* transgenic lines using qRT-PCR (see **Figure 9C**). The localisation of MYB112-GFP fusion protein in roots of ten-day old *35S:MYB112-GFP3* and *35S:MYB112-GFP4* transgenic seedlings was analysed under the fluorescence microscope. GFP fluorescence was exclusively present in nuclei (**Figure 10A**), consistent with the role of MYB112 as a TF.

#### **Conclusion: MYB112 is a Nuclear Protein**

#### b. Tissue-specific Expression of *MYB112*

To investigate *MYB112* expression at the tissue level, a ~1.3-kb long 5' upstream regulatory region, including the 5'-UTR, was transcriptionally fused to the  $\beta$ -glucuronidase (*GUS*) reporter gene and the resulting construct, *Pro<sub>MYB112</sub>:GUS* in the pCAMBIA1305 vector, was transformed into *Arabidopsis thaliana* by *Agrobacterium*-mediated transformation.

**Figure 10. Localisation of *MYB112* expression.**

**(A)** Subcellular localization of MYB112-GFP fusion protein in roots of transgenic *Arabidopsis*. 1, Bright field. 2, GFP fluorescence. 3, Merged. Arrows indicate the presence of MYB112-GFP protein in the nuclei. **(B)** GUS activity in *Arabidopsis thaliana* *Pro*<sub>MYB112</sub>:GUS seedlings. 1, Ten-day-old seedling. GUS staining is mainly localized to cotyledons. Staining is also visible in the tip and margin regions of leaves number one and two (arrow). 2 - 5, 14-day-old seedlings. 2 and 3, GUS activity in leaves one and two. 4, GUS staining in hydathodes of leaf six (arrows). 5, Lateral root. 6 - 14, three- to six-week-old plants. 6, GUS activity in a young rosette leaf is restricted to hydathodes (arrows). 7, GUS activity in mature rosette leaves is often absent from the leaf edges, with the exception of hydathodes (zoom in 9) and the trichome base (zoom in 10); also the mid vein remains unstained (zoom in 11). 8, Strong GUS staining in a senescent leaf. 12, No detectable GUS expression in a flower bud. 13, GUS activity in a mature flower. 14, GUS staining in stigma and the internode of gynoecium (abscission zone) (arrows). 15, No staining in a young anther. 16, Intense GUS staining in a mature anther and pollen grains (zoom in 17). Staining was performed for ~1-2 h.

GUS activity driven by the *MYB112* promoter was tested in five independent transgenic lines of T2 and T3 generations. Representative expression patterns are shown in **Figure 10B**. Expression of the *MYB112* gene was observed in most tissues both, in young seedlings and throughout plant development. At approximately ten days after sowing (DAS), GUS activity was detected in cotyledons and in the margins of the first leaves, where hydathodes are localised (**Figure 10B.1**). Hydathodes enable water conduction (Candela *et al.*, 1999). By two weeks, the following rosette leaves were fully expanded and displayed relatively strong GUS activity, while GUS staining was restricted to hydathodes in recently emerged leaves (**Figure 10B.2-4**). GUS expression was also detected in lateral roots of young seedlings (**Figure 10B.5**). In older plants, GUS activity was observed in both leaves and flowers. Young rosette leaves, like young seedling leaves, exhibited gene expression exclusively in hydathodes (**Figure 10B.6** and **10B.9**). In mature rosette leaves GUS staining was also detected at the base of trichomes and around the mid vein (**Figure 10B.7** and **10B.10**), however no GUS activity was observed in the mid vein itself (**Figure 10B.7** and **10B.11**). The strongest GUS signal was observed in old rosette leaves, demonstrating that *MYB112* is a senescence-associated gene (SAG; **Figure 10B.8**); this finding is in accordance with previous reports that found elevated *MYB112* transcript abundance in senescing leaves compared to non-senescent leaves, as determined by microarray hybridizations and quantitative real-time PCR (qRT-PCR) (Balazadeh *et al.*, 2008; Breeze *et al.*, 2011). Staining in the floral parts was mainly localised to anthers and pollen (**Figure 10B.13** and **10B.16** and **17**). Immature floral

tissue showed no GUS activity (**Figure 10B.12** and **10B.15**), consistent with virtually undetectable *MYB112* expression on microarrays (see eFP browser; <http://bar.utoronto.ca/efp>). *GUS* expression was also noted at the stigma and bottom end (later fruit abscission zone) of the gynoecium (**Figure 10B.14**).

### 3.3. Identification of MYB112 Early Responsive Genes

#### a. Expression Profiling after Short-term Induction of *MYB112* Expression in *MYB112-IOE* Plants

To identify downstream target genes of the MYB112 TF and thus define its regulatory network, we used two-week-old *MYB112-IOE* plants and tested EST-dependent *MYB112* expression 1 h, 3 h and 5 h after EST treatment. As controls we either used DMSO-treated *MYB112-IOE* lines or EST-treated empty-vector plants. *MYB112* expression increased strongly (by up to ~115-fold) already within 1 h of EST treatment, further increased after 3 h (to ~294-fold), and reached its maximum (~765-fold) 5 h after EST application (**Figure 11**). To find genes responsive to MYB112, two-week-old *MYB112-IOE* seedlings were transferred to liquid MS medium containing either 10  $\mu$ M EST or DMSO as control. Seedlings were harvested 3 h and 5 h after EST induction and after removal of the roots were subjected to expression profiling using Affymetrix ATH1 arrays. By including the wild-type control line in our analyses we could distinguish between genes responding solely to the EST treatment from those responding to elevated *MYB112* expression. Two independent experiments were performed and analysed from the 5 h time point (*MYB112-IOE-5* h), and one experiment from the 3 h time point (*MYB112-IOE-3* h). Statistical tests using the Limma Bioconductor package (Gentleman *et al.*, 2004) allowed us to identify 56 genes that were significantly differentially expressed (>2-fold) upon 5 h induction of *MYB112*, of which 28 were up- (**Figure 12, Table 2**) and 28 were down-regulated (**Figure 12, Table 1**), excluding the EST-responsive genes in wild-type plants (see Gene Expression Omnibus, <http://www.ncbi.nlm.nih.gov/geo/>, accession no. GSE36721).

**Figure 11. Expression level of *MYB112* in estradiol-treated *IOE* plants.**

Two-week-old *Arabidopsis MYB112-IOE* seedlings were treated for 1 h, 3 h and 5 h with estradiol in liquid MS medium supplemented with 1% sucrose. As controls, DMSO-treated *MYB112-IOE* plants were used. Average log<sub>2</sub> values  $\pm$  SD measured by qRT-PCR are shown (n = 3).

Among the up-regulated genes three encoded TFs, namely *MYB32*, *MYB7* and *MYB6*. Interestingly, all three TFs belong to the same subgroup 4 of the R2R3-MYB family. MYB factors of this subgroup were shown to be involved in the regulation of flavonoid and lignin biosynthesis in *Arabidopsis* (Preston *et al.*, 2004; Zhong and Ye, 2012). *UGT84A2* is another gene with a function in phenylpropanoid biosynthesis and modification, and was up-regulated after 5 h of *MYB112* induction. *UGT84A2* is a sinapic acid-O-glucosyltransferase (Sinlapadech *et al.*, 2007) that plays a major role in providing sinapoyl-glucose for anthocyanin sinapoylation (therefore being highly important in the production of the anthocyanin derivative A11; Yonekura-Sakakibara *et al.*, 2012). Moreover *MYB32*, *MYB7* and *UGT84A2* were previously shown to be up-regulated during age-dependent senescence in wild-type *Arabidopsis* (Buchanan-Wollaston *et al.*, 2005; Balazadeh *et al.*, 2008; GENEVESTIGATOR). Besides *MYB32*, *MYB7* and *UGT84A2*, eleven other upregulated transcripts (representing half of the *MYB112* up-regulated genes, see **Table 2**) were previously reported to be senescence-associated (eFP browser; Winter *et al.* 2007, Balazadeh *et al.*, 2008;

Breeze *et al.*, 2011; <http://www2.warwick.ac.uk/fac/sci/lifesci/research/prestadata/senescence>). This result supports the model that MYB112 is a senescence-regulatory TF and that expression of several known senescence-associated genes (including TFs) is regulated by this MYB TF. In the single 3 h Affymetrix experiment we identified (>4-fold) 15 differentially expressed genes (one up-, and 14 down-regulated; see Gene Expression Omnibus, accession no. GSE36721). There was an overlap of one up-regulated gene (*MYB7*) and seven down-regulated genes at both 3 h and 5 h after *MYB112* induction (**Figure 12**). We next tested the expression of 28 genes up-regulated after 5 h of EST treatment, using qRT-PCR and could confirm expression changes for 22 of the 28 up-regulated genes in RNA samples from a third, independent biological experiment (**Table 2**).

**Figure 12. Identification of MYB112 early responsive genes.**

The number of up- and down-regulated genes in *MYB112-JOE* two-week-old seedlings treated with estradiol for 3 h (one biological replicate) or 5 h (two biological replicates) as measured using Affymetrix ATH1 microarray. Cut off 4-fold and 2-fold was used for the 3 h and 5 h experiment, respectively.

**Table 1. MYB112-dependent down-regulated genes.**

Change in expression of genes after 3 h (one replicate) and 5 h (two replicates) of *MYB112* induction in EST-treated *MYB112-IOE* seedlings as measured by microarray expression profiling (Affymetrix ATH1) and qRT-PCR. Data are shown as log<sub>2</sub> values normalised to mock treated control plants. SD, standard deviation; n.t., not tested. Hypoxia-responsive genes are shown in red (Liu *et al.*, 2005; Licausi F., personal communication).

Interestingly, we noted that ten of the MYB112 down-regulated genes, were previously described as hypoxia-responsive (Liu *et al.*, 2005; Licausi F., personal communication). These include seven genes common for the 3 h and 5 h induction and three genes responding after 5 h EST treatment (see **Table 2**). According to the available gene expression data (i. e. Genevestigator, publications), expression of *MYB112* does not change upon hypoxia or anoxia, or after reoxygenation. However, transcript level is only one part of the regulatory process; factors such as RNA stability, translation rates, protein processing and stability and many others are likely to have essential roles in the moderation of MYB112 cellular activity. We therefore designed qRT-PCR primers for 50 genes previously described as hypoxia-responsive (Liu *et al.*, 2005) and measured their expression in *MYB112-IOE* seedlings treated with EST for 5 h. We could confirm the decreased transcript level of nine genes shown in **Table 1**, using RNA from an independent biological experiment. Moreover, we found that expression of additional four hypoxia-responsive genes was decreased in transgenic plants in comparison to DMSO-treated plants (see **Supplementary Table 1**). The relation between MYB112 and decreased expression of hypoxia-responsive genes is currently unclear and requires further investigation.

#### **Conclusion: MYB112 Acts as Both Positive and Negative Regulator of Gene Expression**

##### **b. Transactivation Assay in *Arabidopsis* Mesophyll Protoplasts**

To confirm that MYB112 regulates the expression of genes identified by expression profiling, we assayed the trans-activation capacity of MYB112 on the promoters of *MYB32*, *MYB7* and *MYB6*. These putative downstream target genes were selected from the dataset considering their function as TFs. Interestingly enough, all three TFs belong to subgroup 4 of the R2R3-MYB family.

**Figure 13. Transactivation assay in *Arabidopsis* mesophyll protoplasts.**

Transactivation of **(A)** *MYB7*, **(B)** *MYB32* and **(C)** *MYB6* expression by MYB112 in *Arabidopsis* mesophyll cell protoplasts. The  $Pro_{MYB7}:fLUC$ ,  $Pro_{MY32}:fLUC$ , or  $Pro_{MYB6}:fLUC$  constructs harbouring the respective promoters (~1.7 kb) upstream of the firefly (*Photinus pyralis*) luciferase (fLUC) open reading frame were co-transformed with the  $35S:MYB112$  plasmid (omitted in control experiments). The  $35S:rLUC$  vector was used for transformation-efficiency normalization. Given are means  $\pm$  SD of five independent transformations. Asterisks indicate significant differences to control as determined by Student's *t*-test,  $p < 0.05$ .

MYB factors of this subgroup were shown to be involved in the regulation of flavonoid and lignin biosynthesis in *Arabidopsis* (Preston *et al.*, 2004; Zhong and Ye, 2012). Mesophyll cell protoplasts were prepared from wild-type (Col-0) *Arabidopsis* leaves and transiently transformed with constructs expressing *MYB112* under the control of the Cauliflower Mosaic Virus (CaMV) 35S promoter. Simultaneously, protoplasts were transfected with vectors carrying the firefly (*Photinus pyralis*) luciferase open reading frame fused to the upstream sequences of the selected *MYB112* target genes. For normalization, protoplasts were additionally transformed with a third construct expressing the *Renilla* luciferase from the 35S promoter. Protoplasts lacking the 35S:*MYB112* effector construct served as controls. *MYB7* and *MYB32* promoters displayed over 3-fold and *MYB6* ~2-fold induction of the reporter gene when *MYB112* was overexpressed in the protoplasts (**Figure 13**).

### c. Expression in *myb112* T-DNA Insertion Mutants

**Figure 14. Expression of *MYB32*, *MYB7* and *MYB6* in *myb112* T-DNA insertion lines.**

Transcript levels of *MYB32*, *MYB7* and *MYB6* in wild-type, *myb112-1* and *myb112-2* mutant two-week-old seedlings as measured by qRT-PCR. Data are represented as  $40-\Delta C_t$ , where  $\Delta C_t$  is equal to  $C_{t \text{ gene\_of\_interest}} - C_{t \text{ reference\_gene\_ACTIN}}$ . Data are means of three replicates  $\pm$  SD. Asterisks indicate statistically significant differences to wild type (Wt) as determined by Student's *t*-test,  $p < 0.05$ .

In addition, we measured transcript abundance of *MYB32*, *MYB7* and *MYB6* in *MYB112* mutants grown for two weeks on MS medium supplemented with 1% sucrose. Expression of both, *MYB32* and *MYB7* was decreased in the *myb112-1* and *myb112-2* lines by ~9- and ~3-fold, respectively. Expression of *MYB6* remained unchanged (**Figure 14**), possibly due to functional redundancy of upstream regulatory TFs. However, taken together the microarray and transactivation assay data confirm a regulatory function of *MYB112* towards *MYB32*, *MYB7* and *MYB6*.

**Conclusion: MYB112 Triggers the Expression of MYB32, MYB7 and MYB6; R2R3-MYB Transcription Factors of Subgroup 4**

#### 3.4. Identification of MYB112 Direct Target Genes

##### a. Identification of the MYB112 DNA Binding Site

In order to estimate the location of a putative *MYB112* binding site within the *MYB32* promoter we used Imap (Infrared mediated mapping of TF binding sites) - a method recently established in our group. The *MYB32* promoter was divided into three 300 bp long DNA fragments and each fragment was labeled with an infrared dye (IRD). Obtained labeled DNA fragments (I-IRD: to around 300 bp upstream the ATG start codon, II-IRD: from - 300 bp to - 600 bp, and III-IRD from - 600 bp to - 900 bp, see **Figure 15**) were next incubated with *in vitro* expressed *MYB112*-GST fusion protein. After subsequent washing steps, the amount of DNA bound to the protein was assessed by measuring the IRD signal intensity (**Figure 15**). Control experiments were performed using GST instead of the *MYB112*-GST fusion protein. Strong IRD signal was detected in case of the I-IRD fragment which was compromised in the presence of its non-labeled version (1:1 ratio, competition experiment). This result indicates that *MYB112* recognises a specific sequence within the - 600 to - 900 bp promoter region upstream of the translation initiation site.

**Figure 15. Infrared mediated mapping of TF binding sites (Imap).**

MYB112-GST fusion protein was expressed *in vitro* using *E. coli* lysate and incubated with three infrared labeled fragments of the MYB32 promoter (each ~300 bp long). After washing and protein-DNA complex precipitation, IRD signal intensity was measured. For competition experiments, non-labeled DNA fragments were used (1:1 ratio). As control, GST was used instead of the MYB112-GST fusion protein. Average values  $\pm$  SD are shown for two independent experiments.

Simultaneously, in collaboration with Gang-Ping Xue (CSIRO Plant Industry, Brisbane, Australia), we performed an *in vitro* binding site (BS) selection experiment to identify sequence motifs recognized by MYB112 using the CELD-transcription factor fusion method (Xue, 2002; Xue, 2005). MYB112 was translationally fused to the catalytic domain of a 6xHIS-tagged cellulase D (CELD) from *Neocallimastix patricairum*. CELD is a highly reactive cellulase enzyme. The MYB112-CELD-HIS fusion under the control of a *tac* promoter (*Ptac*) was transformed to XL1-Blue strain of *E. coli*. Positive clones, containing the in-frame fusion, were identified using carboxymethyl (CM)-cellulose as a substrate. This substrate was added to the *E. coli* Luria Broth (LB) medium and was hydrolysed only by positive clones. The hydrolysis of cellulose was visualized by Congo Red staining (**Figure 16A**). The MYB-CELD-HIS fusion protein was next purified from the positive clones using a 1-mL Ni<sup>2+</sup> column (GE Healthcare, Munich, Germany) coupled to an Äkta-Purifier FPLC system (GE Healthcare). Aliquots of the flow-through fractions were analysed by electrophoresis on 12% polyacrylamide gel (SDS-PAGE) and Coomassie staining (**Figure 16B**).

**Figure 16. Screening for cellulase-positive MYB112-CELD-HIS clones.**

**(A)** MYB112-CELD-HIS expressing *E. coli* colony grown on carboxymethyl (CM)-cellulose-containing medium after Congo Red staining. Due to the CELD activity CM-cellulose present in the medium is hydrolysed and this effect is visualised by Congo Red staining (note the light hallow indicated by an arrow). **(B)** MYB112-CELD-HIS protein (~70 kDa) was purified from *E. coli* lysates of cellulose-positive clones using a 1-mL Ni<sup>2+</sup> column (GE Healthcare, Munich, Germany) coupled to an Äkta-Purifier FPLC system (GE Healthcare). Aliquots of the flow-through fractions were analysed by electrophoresis on 12% polyacrylamide gel (SDS-PAGE) and Coomassie staining. The first line on the gel represents separation of the marker

peptides (M). The second line contains proteins that did not bind to the Ni<sup>2+</sup>-agarose beads (unbound fraction). The two following lines contain proteins washed away during two washing steps. In the fourth line, MYB112-CELD-HIS protein is separated.

Expressed and purified recombinant MYB112-CELD-HIS protein was incubated with biotin-labeled random-sequence oligonucleotide probes (performed by Gang-Ping Xue). Oligonucleotides bound by the MYB112-CELD-HIS fusion protein were recovered by means of affinity purification of the DNA-MYB112-CELD-HIS complex and amplified using PCR (Xue, 2002; Xue, 2005). Next, the amplified DNA fragments were cloned into bacteria and sequenced (**Figure 17A**). Twenty nine sequences were obtained and analysed for binding activity. An alignment of the target sequences is shown in **Figure 17B**. MYB112 binds to an 8-bp DNA fragment containing the consensus sequence (A/T/G)(A/C)CC(A/T)(A/G/T)(A/C)(T/C). The identified MYB112 recognition site is present in promoters of genes up-regulated by MYB112 in estradiol-inducible overexpression lines (**Table 2, Supplementary Data 1**), including *UGT84A2* (one BS at ~-1.6 kb counted from the translation initiation codon) and the three MYB genes (within the 1-kb upstream regions): *MYB32* (two BSs), *MYB7* (one) and *MYB6* (three). One of the two MYB112 recognition sites identified within the *MYB32* promoter is localised at position -777 bp, i.e. within the region previously selected using Imap (**Figure 15**). The second BS is located at the position -986 bp, so beyond the analysed region of -900 bp. The MYB112 BS identified here is similar to the MYB consensus motif: (A/C)ACC(A/T)A(A/C)C (Sablowski *et al.*, 1994) identified as *cis* element responsible for the binding of MYB proteins in the anthocyanin pathways in *Antirrhinum* (Sablowski *et al.*, 1994; Tamagnone *et al.*, 1998) and maize (Grotewold *et al.*, 1994).

In addition, the MYB112 BS is not present within the 1-kb promoter regions of MYB112-dependent down-regulated hypoxia-responsive genes. This indicates an indirect effect of MYB112 on the expression of these genes through activation of other TFs.

**Figure 17. Identification of MYB112 DNA binding site.**

(A) Schematic representation of the *in vitro* binding site selection experiment. (B) Alignment of 29 sequences derived from oligonucleotides bound to MYB112-CELD-HIS fusion protein after *in vitro* binding site selection. (C) A motif common for 29 positive clones identified using MEME. The selected motif is present in the promoters of putative direct target genes.

**Conclusion: MYB112 BS is Present within the Promoters of Genes Encoding R2R3-MYB Factors of Subgroup 4 and UGT84A2**

**Table 2. MYB112-dependent up-regulated genes with indicated number of MYB112 binding sites (BS).**

Change in expression of genes after 3 h (one replicate) and 5 h (two replicates) of *MYB112* induction in EST-treated *MYB112-IOE* seedlings as measured by microarray expression profiling (ATH1) and qRT-PCR. Data are shown as log<sub>2</sub> values normalised to mock-treated control plants. Right column (BS) shows the number of MYB112 binding sites within 1-kb promoter region. SD, standard deviation. Senescence-associated genes (SAGs) are shown in red (eFP browser; Winter *et al.* 2007; Balazadeh *et al.*, 2008; Breeze *et al.*, 2011; <http://www2.warwick.ac.uk/fac/sci/lifesci/research/prestadata/senescence>).

#### b. EMSA and ChIP Assay

We next employed an electrophoretic mobility shift assay (EMSA) to test *in vitro* the physical interaction between MYB112 protein and promoter fragments of *MYB6*, *MYB7* and *MYB32*. Expressed and purified MYB112-CELD-HIS protein was incubated with infrared dye (IRD)-labeled 40-bp long promoter fragments of the selected putative target genes containing the identified MYB112 binding site (BS). The probes included the single MYB112 BS of the *MYB7* promoter (fragment *MYB7\_1*), either of the twoBSs of the *MYB32* promoter (*MYB32\_1* or *MYB32\_2*), or two neighboring sites of the three present in the *MYB6* promoter (both included in *MYB6\_1/2* fragment). Locations of the BSs within the promoters of target genes are shown in the **Supplementary Data 1**. After incubation of the fusion protein with respective IRD-labeled promoter fragments, DNA-protein complexes were separated on 6% retardation gel and the IRD signal was detected using the Odyssey Infrared Imaging System from LI-COR Biosciences (Bad Hamburg, Germany). Retardation of DNA movement through the gel (the shift) indicates interaction between the DNA fragment and the DNA-binding protein. This effect is abolished in the presence of an unlabeled version of the DNA fragment (competitor). In the presence of MYB112-CELD-HIS, the IRD-labeled promoter fragments of *MYB6*, *MYB7* and *MYB32* were shifted on the gel (**Figure 18A**, line 2) as compared to the fragments migrating in the absence of the fusion protein (**Figure 18A**, line 1). Binding between the protein and IRD-labeled probes is compromised in the presence of unlabeled versions of the promoter fragments (200-fold molar excess), indicating that MYB112 binding activity is specific. These results indicate a physical interaction of MYB112 with the *MYB6*, *MYB7* and *MYB32* promoters.

Finally, to verify MYB112 binding to the respective promoters *in vivo*, we performed chromatin immunoprecipitation coupled to quantitative polymerase chain reaction (ChIP-qPCR) using plants bearing a *35S:MYB112-GFP* construct (accumulating MYB112-GFP fusion protein in the nucleus, see **Figure 5A**). We designed primers flanking the MYB112 binding sites of the different promoters and measured their abundance using qPCR. As shown in **Figure 18B**, the *MYB32* (binding site 2) and *MYB7* promoter fragments containing the selected *cis* element were enriched relative to control, proving direct binding of MYB112. In contrast, we did not detect significant

binding of MYB112 to the *MYB6* and *UGT84A2* promoters. It may, however, be that these two genes are targets of MYB112 in other physiological conditions that we did not test in our experiments. Taken together, our data firmly prove that MYB112 acts as a direct transcriptional regulator of *MYB32* and *MYB7*.

**Figure 18. Electrophoretic mobility shift assay (EMSA) and chromatin immunoprecipitation (ChIP) assay.**

**(A)** Electrophoretic mobility shift assay (EMSA). Purified MYB112-CELD-His protein binds specifically to the MYB112 binding sites present in the *MYB6*, *MYB7* and *MYB32* promoters. *In vitro* DNA binding reactions were performed with 40-bp double-stranded oligonucleotides including the MYB112 binding sites of the respective target gene promoters. The DNA fragments were labeled with infrared dye (IRD). The fragments contained two (*MYB6\_1/2*) or one (*MYB7*, *MYB32\_1* and *MYB32\_2*) MYB112 binding motif. 1, IRD-labeled DNA fragment. 2, MYB112 protein with labeled DNA fragment. Note distinct shift indicating binding. 3,

MYB112 protein, labeled DNA fragment and 200 x excess competitor. Note the shift disappearance. **(B)** ChIP-qPCR. Whole shoots of two-week-old *Arabidopsis* seedlings expressing GFP-tagged MYB112 under the control of 35S CaMV promoter (35S:MYB112-GFP) and wild-type plants were harvested for the ChIP experiment. Enrichment of the respective promoter fragments was quantified by qPCR. Primers annealing to promoter regions of two *Arabidopsis* genes lacking MYB112 binding sites, i.e. *At2g22180* (Neg1) and *At3g1840* (Neg2), were used as negative controls. Data represent means  $\pm$  SD of three independent experiments. Asterisks indicate statistically significant differences to controls as determined by Student's *t*-test,  $p < 0.05$ . Enrichment of *MYB7* and *MYB32* promoter fragments is detected.

### **Conclusion: MYB112 Binds to the *MYB7* and *MYB32* Promoters *in vitro* and *in vivo***

#### **3.5. Flavonoid Accumulation in *MYB112* Transgenic Plants**

The two identified direct MYB112 target genes, i.e. *MYB32* and *MYB7*, like *MYB112* itself, are both senescence-associated. The two candidates were previously proposed to play a role in the regulation of the flavonoid biosynthesis pathway, i.e. anthocyanin and lignin production (Preston *et al.*, 2004; Zhong and Ye, 2012). In order to analyse the possible role of *MYB112* in controlling flavonoid accumulation in plants, we generated estradiol (EST)-inducible overexpression (*MYB112-IOE*) lines using the pER8 vector developed by Zuo *et al.* (2000) and induced its expression with 10  $\mu$ M EST in seedlings grown in liquid MS medium supplemented with 1% sucrose. As controls we used DMSO-treated *MYB112-IOE* lines or EST-treated empty-vector plants. After 5 days of EST treatment, leaves of *MYB112-IOE* seedlings accumulated anthocyanins, whereas mock-treated plants (DMSO) (**Figure 19A**) as well as EST-treated empty-vector plants (not shown) did not. At shorter induction times (i.e., 5 h) no anthocyanin accumulation was observed in *MYB112-IOE* lines (not shown), indicating that MYB112 is not immediately upstream of anthocyanin pathway genes. We extracted and measured the anthocyanin level in *MYB112-IOE* seedlings of two lines (IOE#1 and IOE#2). Interestingly, the two *MYB112-IOE* lines accumulated 23- and 29-fold more anthocyanins than mock-treated plants (**Figure 19B**). We next analysed the flavonoid metabolite profiles of *MYB112-IOE* seedlings using liquid chromatography coupled to mass spectrometry (LC-MS). Compared with

DMSO-treated plants, EST-induced seedlings showed a significant increase in the content of two cyanidin derivatives, namely cyanidin-3-O-[2-O-(2-O-(sinapoyl)-xylosyl)-6-O-(*p*-O-coumaroyl)-glucoside]-5-O-[6-O-(malonyl)-glucoside] (A11; **Figure 19C**) and cyanidin-3-O-[2''-O-(xylosyl)-6''-O-(*p*-O-(glucosyl)-*p*-coumaroyl) glucoside]-5-O-[6'''-O-(malonyl)-glucoside] (A8; Tohge *et al.*, 2005, **Figure 19D**). Other cyanidin derivatives were not reliably detected in the samples. Flavonol glycosides derived from kaempferol (named F1 to F3, according to Tohge *et al.*, 2005) were reduced (**Figure 19E**), whereas the levels of flavonoid glycosides derived from quercetin (named F5 and F6) accumulated in EST-treated plants (**Figure 19F**) in comparison to control plants.

We next measured the expression of genes encoding enzymes involved in flavonoid biosynthesis as well as regulatory genes in *MYB112-IOE* seedlings treated with EST for 5 days (**Figure 19G**, **Figure 20** and **Supplementary Table 2**). Transcript levels of *PHENYLALANINE AMMONIA LYASE (PAL)* and *CINNAMATE-4-HYDROXYLASE (C4H)*, genes associated with the pathway of phenylpropanoid biosynthesis, remained unchanged in the EST-treated seedlings. *CHALCONE SYNTHASE (CHS)* and *CHALCONE ISOMERASE (CHI)* were slightly down-regulated (~2-fold). Transcript levels of the genes *DIHYDROXYFLAVONOL-4-REDUCTASE (DFR)* and *ANTHOCYANIDIN SYNTHASE (ANS, LDOX)* were substantially increased in seedlings overexpressing *MYB112*. DFR catalyses the conversion of dihydroquercetin to leucocyanidin, and ANS encodes a dioxygenase that operates downstream of DFR and catalyses the conversion of leucocyanthocyanidins to anthocyanidins. In addition to the anthocyanin biosynthesis genes indicated above, several genes proposed to be involved in the production of specific anthocyanin derivatives were up-regulated. These include three glycosyltransferase family genes, namely *UGT79B1 (A3G2''XT, anthocyanin-3-O-glucoside-2''-O-xylosyltransferase*; Yonekura-Sakakibara *et al.*, 2012), *UGT84A2 (SGT, sinapic acid 1-O-glucosyltransferase)* and *UGT75C1 (A5GT, anthocyanin-5-O-glucosyltransferase*; Tohge *et al.*, 2005), and the acyltransferase family gene *A5GMaT (At3g29590, anthocyanin-5-O-glucoside-6''-O-malonyltransferase*; D'Auria *et al.*, 2007) and the glutathione-S-transferase family gene *TT19*.

Figure 19. Overexpression of *MYB112* causes changes in flavonoid content.

(A) *MYB112-IOE* seedlings treated with 10  $\mu$ M estradiol for 5 days accumulate red pigment in the middle of the leaves spreading to the edges (arrows and magnified image). (B) Total anthocyanin content was measured spectrophotometrically after extraction with HCl solution ( $ABS_{535-(650 \times 2.2)} / \text{mg}$  frozen weight). Mean value  $\pm$  SD of five replicates is shown. (C) LC-MS analysis of A11 and (D) A8 content (Tohge *et al.*, 2005) in mock- and estradiol-treated *MYB112-IOE*. (E) LC-MS analysis of flavonol content (F1 - kaempferol 3-O-rhamnoside 7-O-rhamnoside, F2 - kaempferol 3-O-glucoside 7-O-rhamnoside, F3 - kaempferol 3-O-[2"-O-(rhamnosyl) glucoside] 7-O-rhamnoside and (F) F5 - quercetin 3-O-glucoside 7-O-rhamnoside and F6 - quercetin 3-O-[2"-O-(rhamnosyl) glucoside] 7-O-rhamnoside. For (C - F) mean values  $\pm$  SD are shown for three replicates. Asterisks indicate statistically significant differences as compared to DMSO-treated plants determined by Student's *t*-test,  $p < 0.05$ . (G) Transcript levels of selected enzymatic (*ANS*, *DFR*, *TT19*, *A3G2"XT*, *UGT84A2*, *A5GMaT*, *A5GT* and *FLS*) and regulatory (*PAP1*, *MYB114*, *MYB111* and *MYB12*) genes involved in anthocyanin and flavonol biosynthesis in *MYB112-IOE* seedlings. Data are represented as  $40-\Delta C_t$ , where  $\Delta C_t$  is equal to  $C_{t \text{ gene\_of\_interest}} - C_{t \text{ reference\_gene\_Actin}}$ . Mean values  $\pm$  SD are shown for three replicates.

The genes encoding glycosyltransferases and acyltransferases catalyze modification reactions for the formation of the most extensively modified A11 anthocyanin (Tohge *et al.*, 2005; D'Auria *et al.*, 2007; Yonekura-Sakakibara *et al.*, 2012). *TT19* is required for vacuolar sequestration of anthocyanins (Kitamura *et al.*, 2004). The transcript level of *FLAVONOL SYNTHASE (FLS)*, which catalyses the synthesis of the flavonols quercetin and kaempferol from dihydroquercetin and dihydrokaempferol, respectively, was down-regulated in the EST-treated *MYB112-IOE* seedlings.

Apart from flavonoid biosynthesis genes, a set of regulatory genes also displayed altered expression in *MYB112* overexpressing plants. Expression of *PAP1* as well as *MYB114* was increased in EST-treated *MYB112-IOE* plants. It should be mentioned however that the *MYB114* gene from the Columbia (Col) accession encodes a putative protein that lacks a transcriptional activation domain due to a stop codon just after the Myb domains (at amino acid 140). The Landsberg *erecta* (Ler) *MYB114* allele encodes a full-length gene and its function in anthocyanin accumulation was confirmed (Gonzalez *et al.*, 2008). *MYB12* and *MYB111*, previously shown to control the expression of genes involved in flavonol biosynthesis, were down-regulated (**Figure 19, Figure 21, Supplementary Table 2**). This suggests that *MYB112* acts through the expression of these regulatory genes.

## Conclusion: Estradiol-inducible Overexpression of *MYB112* Induces Anthocyanin Formation

We next analysed the relative anthocyanin content in the two *myb112* T-DNA insertion mutants using spectrophotometric measurements (**Figure 20A**). Compared to wild-type seedlings, anthocyanin content was reduced by over 27% in the *myb112-1* mutant grown for two weeks on Murashige-Skoog (MS) medium containing 4% sucrose.

**Figure 20. Reduced flavonoid content in *myb112* T-DNA mutants.**

(A) Total anthocyanin content ( $ABS_{535-(650 \times 2.2)}$  / mg frozen weight) and (B) LC-MS analysis of A11 and (C) A8 content (Tohge *et al.*, 2005) in *myb112* mutants in comparison to wild-type seedlings grown on 4% sucrose. (D) LC-MS analysis of flavonols content (F1 - kaempferol 3-O-rhamnoside 7-O-rhamnoside, F2 - kaempferol 3-O-glucoside 7-O-rhamnoside, F3 - kaempferol 3-O-[2"-O-(rhamnosyl) glucoside] 7-O-rhamnoside and (E) F5 - quercetin 3-O-glucoside 7-O-rhamnoside and F6 - quercetin 3-O-[2"-O-(rhamnosyl) glucoside] 7-O-rhamnoside in *myb112* mutants in comparison to wild-type plants. Mean values  $\pm$  SD are shown for five replicates (A) and three replicates (B - E). Asterisks indicate statistically significant differences as compared to wild-type (Wt) plants determined by Student's *t*-test,  $p < 0.05$ . (F) Transcript levels of selected biosynthetic (*ANS*, *DFR*, *A3G2"XT*, *A5GMaT*, *A5GT*, *TT19* and *FLS*) and regulatory (*PAP1*, *MYB114* and *MYB12*) genes involved in anthocyanin and flavonol biosynthesis in two-week-old *myb112-1* seedlings grown on MS medium + 1% sucrose. Data are represented as  $40-\Delta C_t$ , where  $\Delta C_t$  is equal to  $C_t_{\text{gene\_of\_interest}} - C_t_{\text{reference\_gene\_Actin}}$ . Mean values  $\pm$  SD are shown for three replicates.

No difference in total anthocyanin content was observed between wild-type and *myb112-2* plants indicating, that the level of *MYB112* transcript present in this knock-down mutant (**Figure 20A**) is sufficient to sustain normal anthocyanin levels. LC-MS analysis revealed that the changes in the total anthocyanin content in the *myb112-1* mutant are caused by decreased accumulation of A11 (**Figure 20B**) and A8 (**Figure 20C**) derivatives in these plants. We also detected a slight decrease of flavonol accumulation in *myb112-1* seedlings compared to wild-type seedlings (**Figure 20D** and **E**). Expression profiling revealed decreased transcript levels of genes coding for key enzymes of flavonoid biosynthesis (*ANS*, *DFR*, *A3G2"XT*, *A5GMaT*, *A5GT*, *TT19*, and *FLS*) as well as regulatory genes (*PAP1*, *MYB114*, *MYB12*) in the *myb112-1* mutant (**Figure 20F**, **Figure 21** and **Supplementary Table 2**).

### **Conclusion: Silencing of MYB112 Results in Decreased Anthocyanin and Flavonol Content**

An integrated schematic view of the transcriptomic and metabolomic shifts occurring in *MYB112*-modified plants compared to wild type or DMSO-treated *MYB112-IOE* plants is given in **Figure 21**.

Figure 21. Integrated transcriptomics and metabolomics data.

Expression of 23 flavonoid biosynthesis genes and nine TFs as measured by qRT-PCR and metabolite content analysed by LC-MS in *MYB112-IOE* seedlings treated with estradiol for 5 days (left box) and in *myb112-1* mutant (right box). Gene expression level and metabolite content changes against DMSO-treated and wild-type plants, respectively, is indicated by colour (cut off: 2-fold).

### 3.5.1. Salt-dependent Flavonoid Accumulation in *MYB112* Transgenics

It has been previously demonstrated that sucrose is an effective inducer of anthocyanin biosynthesis in *Arabidopsis* seedlings and that the expression of *PAP1* strongly increases upon sucrose treatment (Teng *et al.*, 2005; Sofanelli *et al.*, 2006). In order to investigate the effect of sucrose concentration on *MYB112* expression, we measured its transcript levels in two-week-old seedlings grown on MS medium supplemented with either 1% or 4% sucrose. As shown in **Figure 22A**, no significant change in *MYB112* expression was detected, while the transcript level of *PAP1* increased significantly in plants grown on high-sucrose medium.

**Figure 22. *MYB112* expression is neither affected by sucrose nor nitrogen.**

**(A)** Transcript levels of *PAP1* and *MYB112*, determined by qRT-PCR, in two-week-old seedlings grown on MS medium with 1% or 4% sucrose. Note the absence of an effect of elevated sucrose concentration on *MYB112* expression. The data are represented as  $40-\Delta C_t$ , where  $\Delta C_t$  is equal to  $C_t$  gene\_of\_interest -  $C_t$  reference\_gene\_*ACTIN*. Means of three independent replicates  $\pm$  SD are shown. The asterisk indicates a statistically significant difference compared to control plants as determined by Student's *t*-test,  $p < 0.01$ . **(B)** Expression level of *PAP1* and *MYB112* in plants grown on media with or without nitrogen. Plants were grown in a hydroponic system and after 19 days were transferred to medium without nitrogen source. Gene expression was measured 6 days after the transfer. *MYB112* expression is not affected by nitrogen availability while *PAP1* expression increases by ~8-fold. Data were extracted from Affymetrix ATH1 hybridisations (unpublished) and represent the means  $\pm$  SD of three biological replicates. Numbers indicate log<sub>2</sub> values.

Our result is in agreement with previously published global transcriptome data on of sucrose-responsive genes (Sofanelli *et al.*, 2006; Osuna *et al.*, 2007). Nitrogen deficiency also enhances expression of specific MYB and bHLH transcription factors and accumulation of end products of the flavonoid pathway (Lea *et al.*, 2007; Rubin *et al.*, 2009). Klaus Humbeck (Martin-Luther Universität Halle-Wittenberg, Germany) performed an experiment in which 19-day-old *Arabidopsis* plants grown on full media supplemented with nitrate were transferred to media without nitrogen for six days. Lack of nitrate resulted in leaf yellowing and anthocyanin accumulation. Expression profiling proved, however, that *MYB112* transcript abundance in plants grown for six days on medium with no nitrogen source was comparable to the transcript level in control plants grown on full (nitrogen-sufficient) MS medium (**Figure 22B**, K. Humbeck, personal communication). In the same experiment, as anticipated, *PAP1* expression increased ~8-fold (**Figure 22B**).

#### **Conclusion: Neither Increased Sucrose nor Decreased Nitrogen Level Affect *MYB112* Expression**

According to microarray data obtained from the Genevestigator and eFP databases, expression of *MYB112* increases upon abiotic stress, namely salt stress. To verify salt-induced expression of *MYB112* we employed the *MYB112* promoter-reporter (*GUS*) gene fusion lines; we transferred two-week-old *Pro<sub>MYB112</sub>:GUS* seedlings to MS medium containing NaCl (150 mM, 24 h). Histochemical staining revealed enhanced *GUS* activity in salt-treated seedlings compared with untreated controls (**Figure 23A**). Salt-responsive *MYB112* expression was further confirmed by qRT-PCR in seedlings treated with salt (150 mM NaCl) for 4, 8 and 24 h in liquid medium (**Figure 23B**, treatment performed by Amin Omidbakhshfard). In addition, we grew *Arabidopsis* Col-0 plants in a hydroponic culture system and subjected them to short- and long-term salt stress (150 mM NaCl), as described previously (Balazadeh *et al.*, 2010a; Balazadeh *et al.* 2010b). In short-term experiments, leaves of 28-day-old plants were sampled 6 hours after stress treatment. In long-term stress experiments, leaves were sampled after 4 days of salt treatment at approximately 20% chlorophyll

loss, indicating senescence. Expression of the senescence-specific marker gene *SAG12* (Noh and Amasino, 1999) was not detected in control plants and plants subjected to short-term salt stress, whereas it was induced under long-term salt stress which induces senescence (Balazadeh *et al.*, 2010b). Microarray gene expression profiling revealed no change in *MYB112* transcript level after short-term stress, however, after 4 days of salt treatment, transcript level increased by over 3-fold (Figure 23C, experiment performed by Annapurna Devi Allu). Similar salinity stress-triggered expression changes have previously been observed for many SAGs (Balazadeh *et al.*, 2010a; Balazadeh *et al.*, 2010b).

**Figure 23. Salt-induced expression of *MYB112*.**

(A) Ten-day-old *Arabidopsis Pro<sub>MYB112</sub>:GUS* seedlings #2 and #7 were treated for 72 h with 0 mM NaCl (control) or 150 mM NaCl (+ NaCl) in liquid MS medium. Enhanced GUS staining is visible in salt-treated seedlings (right panel). (B) Transcript level of *MYB112* in wild-type seedlings treated with 150 mM NaCl in liquid culture. Incubation times were 4, 8 and 24 h. The data are represented as  $40 - \Delta C_t$ , where  $\Delta C_t$  is equal to  $C_{t \text{ gene of interest}} - C_{t \text{ reference gene ACTIN}}$ . Mean values of three independent replicates  $\pm$  SD are shown. Asterisks indicate statistically significant differences in comparison to the controls, as determined by Student's *t*-test,  $p <$

0.01. (C) Expression profiling using Affymetrix ATH1 arrays shows elevated *MYB112* transcript abundance in plants grown hydroponically with 150 mM NaCl in comparison to control plants. Plants were harvested after 6 h and 4 days of treatment. The experiment was performed in three independent replications. Numbers on the y axis indicate average log<sub>2</sub> values  $\pm$  SD.

**Conclusion: Expression of *MYB112* is Stimulated by Increased Salt Content**

Figure 24. *MYB112* regulates anthocyanin accumulation during salt stress.

**(A)** Appearance of seedlings treated with salt for three days. Plants were grown on MS medium supplemented with 1% sucrose and after two weeks were transferred to liquid medium containing 150 mM NaCl. Note the lack of red pigmentation in *myb112-1* seedlings. **(B)** Total anthocyanin content was measured spectrophotometrically ( $ABS_{535-(650 \times 2.2)} / \text{mg}$  frozen weight) after extraction with HCl solution. Mean values  $\pm$  SD are shown for three replicates. Asterisks indicate statistically significant differences in comparison to wild-type (Wt) plants as determined by Student's *t*-test,  $p < 0.05$ .

To test whether *MYB112* may be involved in controlling anthocyanin accumulation during salt stress, we transferred ten-day-old seedlings to liquid MS medium containing 150 mM NaCl. After three days, wild-type and *MYB112* overexpression plants (i.e., *35S:MYB112* and *35S:MYB112-GFP* lines) turned red, whereas *myb112-1* mutant plants accumulated visibly less anthocyanin (**Figure 24A**). Spectrophotometric analysis of anthocyanin content in these plants revealed a decrease in total anthocyanin content by 37% in the *myb112-1* mutant compared to wild type. *35S:MYB112* and *35S:MYB112-GFP* plants accumulated ~2.5-fold and ~65% more anthocyanins, respectively, than wild-type plants (**Figure 24B**). We therefore concluded, that *MYB112* contributes to regulating anthocyanin production in response to salinity stress.

### **Conclusion: MYB112 Regulates Anthocyanin Accumulation under Salt Stress**

#### **3.5.2. High light-dependent Flavonoid Accumulation in *MYB112* Transgenics**

TSP9 (Thylakoid-soluble Phosphoprotein of 9 kDa) is a mobile thylakoid protein that interacts with light-harvesting complex (LHC) II and the peripheries of both photosystems. It was shown to regulate light harvesting by facilitating the dissociation of light-harvesting proteins from photosystem II. Upon phosphorylation, TSP9 is partially released from the membrane and therefore was proposed to play a role in chloroplast signalling (Hansson *et al.*, 2007). Global expression profiling identified 23

genes, including *MYB112*, that were high light-dependent in wild-type plants, but not in a *tsp9* T-DNA insertion mutant (GK\_377A12) (**Table 3**; Fristedt *et al.*, 2009). (**Table 3**). This finding suggests a function of *MYB112* in TSP9-dependent high light signalling. To investigate further the relation between the two genes, we measured total anthocyanin content in two *tsp9* T-DNA insertion lines under high light stress. However, anthocyanin accumulation was not affected in these mutants, suggesting that the level of *MYB112* expression in these plants was still sufficient to sustain the wild-type phenotype. To verify high light-induced expression of *MYB112*, we employed the *Pro<sub>MYB112</sub>:GUS* reporter lines. Ten-day-old *Arabidopsis Pro<sub>MYB112</sub>:GUS* seedlings as well as three-week-old plants were treated for 6 h and 20 h, respectively, with high light ( $500 \mu\text{mol m}^{-2} \text{s}^{-1}$ ).

**Table 3. Genes found to be down-regulated in the *tsp9* mutant after 3 h of high light treatment as compared to wild-type plants.**

according to Fristedt *et al.*, 2009

In both cases, histochemical staining revealed enhanced GUS activity in high light-treated plants compared to controls kept in normal light condition ( $100 \mu\text{mol m}^{-2} \text{s}^{-1}$ ) (**Figure 25A, B**). Spectrophotometric analysis of anthocyanin content in three-week-old *myb112* mutants grown under high light condition ( $500 \mu\text{mol m}^{-2} \text{s}^{-1}$ ) for three days showed a ~4-fold decrease in pigment content in *myb112-1* plants (**Figure 26**), suggesting that *MYB112* is involved in high light-induced anthocyanin accumulation.

**Figure 25. High light-induced expression of *MYB112*.**

**(A)** *MYB112* promoter activity in ten-day-old *Arabidopsis Pro<sub>MYB112</sub>:GUS* seedlings #2 and #7 treated for 6 h with high light ( $500 \mu\text{E}$ ; right panel) in comparison to control seedlings grown with  $100 \mu\text{E}$  (left panel). **(B)** GUS activity in three-week-old *Pro<sub>MYB112</sub>:GUS* plants #2 and #7 treated with high light for 20 h (right panel) in comparison to control plants kept in  $100 \mu\text{E}$  (left panel). Note the enhanced GUS staining of plants treated with high light.

**Figure 26. Anthocyanin content in *myb112* T-DNA insertion lines grown under high light condition.**

Plants were grown in long-day conditions and after three weeks were transferred to high light (500  $\mu$ E) for three days. Total anthocyanin content was measured spectrophotometrically ( $ABS_{535-(650 \times 2.2)}$  / mg frozen weight) after extraction with HCl solution. Mean values  $\pm$  SD are shown for five replicates. The asterisk indicates statistically significant difference in comparison to wild-type (Wt) plants as determined by Student's *t*-test,  $p < 0.05$ .

### **Conclusion: MYB112 is a High Light-induced Gene**

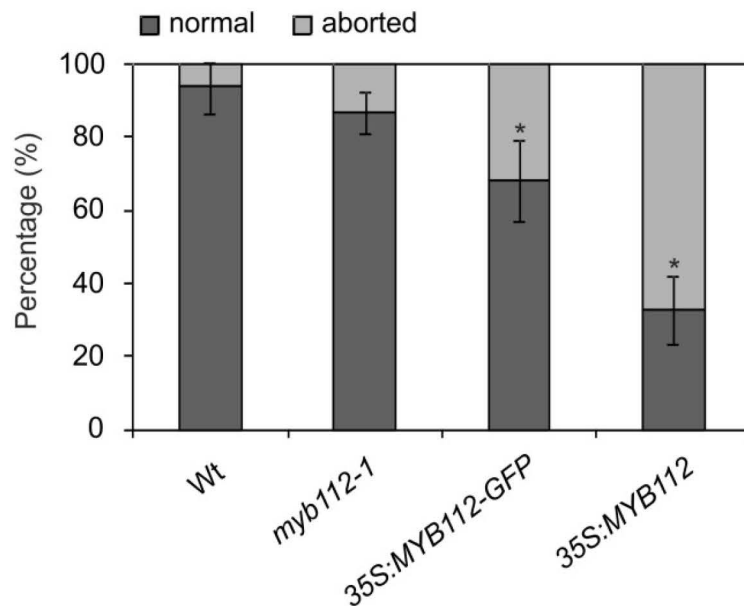

#### **3.6. Pollen Viability of MYB112 Transgenics**

*MYB32*, identified here as a direct MYB112 target gene, as well as the closely related *MYB4* have been reported to influence pollen development, leading to structural distortions and a lack of cytoplasm in pollen of two *myb32* T-DNA insertion lines, as well as in *myb4* dSpm insertion and overexpression lines ((Preston *et al.*, 2004).

**A**

**B**

**Figure 27. Pollen viability in *MYB112* transgenic plants.**

**(A)** Appearance of pollen grains after staining with Alexander dye. Normal pollen grain is purple while sterile pollen stains blue (arrows). Note the increase in the number of aborted pollen in *MYB112* overexpression lines. **(B)** Percentage of viable and aborted pollen in *MYB112* transgenic plants determined after Alexander staining. Pollen was obtained from six plants and six individual microscope images were analysed. Mean values  $\pm$  SD are shown. Asterisks indicate statistically significant difference to wild type (Wt) as determined by Student's *t*-test,  $p < 0.01$ .

Of note, expression of the anthocyanin biosynthesis genes *DFR* and *ANS* decreases in *myb32* knock-out plants and expression of *CAFFEIC ACID O-METHYLTRANSFERASE* (*COMT*) is increased (Preston *et al.*, 2004). *MYB4* suppresses *C4H* encoding Cinnamate-4-Hydroxylase which upstream of the flavonoid-specific pathway converts *trans*-cinnamate into 4-hydroxycinnamate (in the general phenylpropanoid pathway). *MYB4* also suppresses the anthocyanin pathway gene *CHS*, whilst it stimulates *CCoAOMT*, encoding Caffeoyl CoA O-Methyl Transferase which is involved in the biosynthesis of sinapate esters and polymerized phenolic derivatives (Jin *et al.*, 2000). Preston *et al.* (2004) speculate, that changes in expression of flavonoid and phenylpropanoid biosynthesis genes in the *myb32* and *myb4* mutants significantly influence the flux along these pathways, interfering with pollen development by altering structural components of the pollen wall. Sporopollenin is the most likely compound to be affected as it consists of polymerized phenols and fatty acid derivatives. By analysing *MYB112* promoter activity in *Pro<sub>MYB112</sub>:GUS* lines we show that *MYB112* is also expressed in pollen (**Figure 8B.16** and **17**). We therefore tested pollen viability in *MYB112* transgenic plants after staining of flowers with Alexander dye (Alexander, 1969). We found that overexpression of *MYB112* leads to partial pollen sterility; 35% and 70% of pollen was aborted in *35S:MYB112-GFP* and *35:MYB112* overexpression plants, respectively (**Figure 28**). The observed decrease in pollen viability in these lines corresponds to the level of *MYB112* overexpression (~5-fold increase in *35S:MYB112-GFP* and ~15-fold in *35S:MYB112*; **Figure 10**).

**Figure 28. Changes in expression of lignin biosynthesis genes in *MYB112* transgenic plants.**

**(A)** Lignin biosynthesis pathway with indicated biosynthesis enzymes. **(B)** Expression of selected lignin biosynthesis genes in *MYB112-IOE* seedlings treated with estradiol in liquid MS medium supplemented with 1% sucrose for 5 days as compared to mock-treated plants. **(C)** Expression of selected lignin biosynthesis genes in *myb112-1* T-DNA mutant seedlings as compared to wild-type plants. The data are represented as  $40-\Delta C_t$ , where  $\Delta C_t$  is equal to  $C_{t \text{ gene\_of\_interest}} - C_{t \text{ reference\_gene\_Actin}}$ . Data are the means of two biological replicates, measured in two technical replicates each  $\pm$  SD.

We also analysed transcript levels of genes encoding key phenylpropanoid biosynthesis enzymes in the *myb112-1* mutant and the *MYB112-IOE* plants treated with estradiol for 5 days (**Supplementary Table 2**). **Figure 29** shows significant changes in the expression of a number of phenylpropanoid biosynthesis genes in *MYB112* transgenic plants. For example, expression of *CCoAOMT* is increased in plants overexpressing *MYB112* (**Figure 29B**), similar to *MYB4* overexpression plants (Jin *et al.*, 2000). *CCoAOMT* is downregulated in the *myb4* knockout line (Jin *et al.*,

2000) and the *myb112-1* mutant (**Figure 29C**), but is not affected in *MYB32*-modified plants (Preston *et al.*, 2004).

### Conclusion: MYB112 Affects Pollen Viability

#### 3.7. Growth Phenotype of *myb112* T-DNA Mutants and RNAi Plants

We have analysed growth phenotypes of *myb112* T-DNA insertion mutant plants. Plants germinated uniformly and in early stages of vegetative growth there was no visible difference between the phenotype of wild-type (Wt) and mutant plants. Bolting time differed between wild-type and *myb112* mutants, as determined when the main florescence stalk had elongated to 1 cm. Wild-type plants bolted 55 days after sowing (DAS), while the two mutants bolted at 58 DAS, when grown in 12 h/12 h day/night regime in soil (**Figure 29A** and **B**). At this time there was a slight difference in the number of leaves between the genotypes (Wt, 33 leaves; *myb112-1*, 34 leaves; **Figure 29C**).

**Figure 29.** Growth phenotype of *myb112* T-DNA insertion mutants.

(A) Phenotype of *myb112* T-DNA insertion mutants at 60 DAS. Plants were grown in 12 h/12 h day/night conditions. (B) Bolting time of *myb112* mutants. The time (DAS), when the main stalk elongated to 1 cm was recorded. (C) Number of rosette leaves at the bolting time. For (B) and (C), 30 plants were counted to calculate mean values  $\pm$  SEM. Asterisks indicate statistically significant differences to wild type as determined by Mann-Whitney Rank Sum Test,  $p < 0.05$ .

In addition, we analysed the phenotypes of seven *MYB112* RNAi lines. Plants were initially grown on MS medium supplemented with 1% sucrose. After two weeks, seedlings were transferred to soil and grown in long-day conditions (16 h/8 h, day/night). No visible phenotype was observed between RNAi plants and empty vector (EV)-transformed plants during the early developmental stages. However, RNAi lines #2 and #10 showed a strong delay in bolting in comparison to the empty vector plants. Control plants began to bolt at 21 DAS, whereas RNAi lines #2 and #10 started to bolt at 30 and 34 DAS, respectively (Figure 30A and C).

**Figure 30. Growth phenotype of *MYB112* RNAi lines.**

(A) Appearance of transgenic *MYB112* RNAi lines 36 DAS. Plants germinated on MS medium and after 2 weeks were transferred to soil. (B) *MYB112* expression level in EV and RNAi plants determined using qRT-PCR. The data is represented as  $40 - \Delta C_t$ , where  $\Delta C_t$  is equal to  $C_{t \text{ gene\_of\_interest}} - C_{t \text{ reference\_gene\_UBQ10}}$ . Data are means of three independent

experiments  $\pm$  SD. **(C)** Bolting time of *MYB112* RNAi lines. The time (DAS), when the main stalk elongated to 1 cm was recorded and **(D)** the number of rosetta leaves was measured at the bolting time. For **(C)** and **(D)**, 10 plants were counted to calculate mean values  $\pm$  SD. Asterisks indicate statistically significant differences to empty vector (EV) lines as determined by Student's *t*-test,  $p < 0.05$ .

The delay of bolting in the RNAi lines correlated to the level of *MYB112* expression measured by quantitative real-time PCR (qRT-PCR) (**Figure 30B**). We also observed a difference in the number of leaves during bolting between wild-type and transgenic plants. We also observed a difference in the number of leaves at bolting between control plants and transgenics. At this time, empty-vector plants had 8-12 leaves, while RNAi#2 and #10 developed, respectively, 14 and 18 leaves on average per rosette (**Figure 30D**). In this case, the delay of bolting was not caused by the overall delayed growth rate but rather by developmental retardation in the bolting process. The cause of the observed phenotypic changes is unclear, however, it may be related with the decreased level on flavonoid accumulation in *MYB112*-deficient plants (**Figure 20**). It was reported that certain flavonoids modulate auxin signalling in plants (Jacobs and Rubery, 1988; Kuhn *et al.*, 2011). The ability of flavonoids to establish auxin gradients translates into phenotypes with strikingly different morpho-anatomical traits (Taylor and Grotewold, 2005; Peer and Murphy, 2007; Besseau *et al.*, 2007; Buer and Djordjevic, 2009). Flavonoids at the plasma membrane are effective inhibitors of PIN and MDR-glycoproteins, that are involved in the cell-to-cell movement of auxin. In addition, evidence of a nuclear location of flavonoids (as well as of enzymes involved in flavonoid biosynthesis), is consistent with flavonoids being capable of regulating the activity of proteins responsible for cell growth: flavonoids may therefore act as transcriptional regulators (Saslowsky *et al.*, 2005; Naoumkina *et al.*, 2008).

#### **Conclusion: MYB112 Affects Bolting Time**

### 3.8. Does MYB44 Act Upstream of MYB112?

Published literature indicates that the expression of *MYB112* is negatively regulated under conditions of salt stress, but not in control experiments, by MYB44, a member of subgroup 22 of the R2R3-MYB TF family (Jung *et al.*, 2008). Microarray-based expression profiling revealed relatively small differences between wild-type and *35S:MYB44* or *myb44* knock-out plants in the absence of salt stress (Jung *et al.*, 2008). However, following 24 h of salinity stress (250 mM NaCl), a clear difference in global transcriptome patterns was observed between wild type plants and *MYB44* overexpressors. Compared to wild-type plants, 816 genes were higher expressed in the *35S:MYB44* line and 496 genes had lower transcript abundance (>2-fold change). Analysis of the data revealed that *MYB112* was among the down-regulated genes; in two independent experiments *MYB112* expression level after salt stress was ~4- and ~20-fold lower in the *35S:MYB44* line than the wild type. Notably, the expression of *MYB32* and *MYB7*, the two direct MYB112 target genes identified here, was also lower in *35S:MYB44* than wild-type plants during salt stress (Jung *et al.*, 2008; E-ATMX-30; **Table 4**), indicating that MYB44 functions as a direct or indirect negative upstream regulator of *MYB112* expression.

according to Jung *et al.* (2008)

In addition, expression levels of genes encoding proteins associated with anthocyanin biosynthesis, such as *CHS*, *F3H*, *ANS*, *DFR*, *PAP1* and *PAP2*, were decreased in *35S:MYB44* plants upon salt stress (Jung *et al.*, 2008; E-ATMX-30; **Table 4**). It was later reported that 12-day-old *35S:MYB44* seedlings grown on MS medium accumulate less anthocyanin than wild-type plants, particularly after jasmonate treatment, whereas *myb44* knockout plants show elevated levels of anthocyanin (Jung *et al.*, 2010). The phenotype of *MYB44* transgenic seedlings is opposite to that of *MYB112* transgenics (see **Figure 19** and **20**). This finding provides further support for the negative regulation of *MYB112* expression. Moreover, bolting time is affected in *35S:MYB44* plants. Wild-type plants bolt earlier than *35S:MYB44* overexpressors and the number of rosette leaves at bolting time is higher in these plants compared to wild type (Jung *et al.*, 2008). A similar phenotype is evident in *myb112* T-DNA mutant and *MYB112* RNAi plants (see **Figure 29** and **30**), consistent with the model that *MYB112* expression is under negative control of *MYB44*.

**Figure 31. Negative regulation of *MYB112* expression by *MYB44*.**

Two-week-old *Arabidopsis* *MYB44-IOE* seedlings (lines #1, #2, #3 and #4) were treated with estradiol for 5 h and then for an additional 2 h with 150 mM NaCl in liquid MS medium supplemented with 1% sucrose. Numbers on the y axis indicate log<sub>2</sub> fold-change (FCh) expression ratio compared to control conditions. Data are the means of three biological replicates  $\pm$  SD, measured by qRT-PCR.

To verify the model, we generated estradiol-inducible *MYB44* overexpression (*MYB44-IOE*) plants and treated transgenic seedlings for 5 h with estradiol in the absence of salt stress, and then induced salt stress (150 mM NaCl) for 2 h (in presence of estradiol). Using qRT-PCR we detected decreased *MYB112* expression in two out of four tested lines (**Figure 31**), indicating that the regulation of *MYB112* expression by *MYB44* may be indirect and may require additional factors, modulating this regulation.

### 4. General Discussion and Outlook

Systematic analysis of mutant plants with impaired expression of R2R3-MYB proteins in *Arabidopsis* as well as in other species resulted in rapid increase in our understanding of their function in plants. R2R3-MYB factors were reported to play roles mainly in regulation of secondary metabolism, plant cell shape and plant organ development (Mandaokar *et al.*, 2006; Baumann *et al.*, 2007; Dubos *et al.*, 2010). A number of R2R3-MYB TFs were described as regulators of flavonoid production. Flavonoid biosynthesis is unique to plants and plays an essential role in their adaptation to sedentary life in a changing environment. These compounds are crucial for the symbiotic plant-microbe interactions and male fertility by promoting the pollen tube development (Koes *et al.* 1994; Hassan and Mathesius, 2012; Ma *et al.*, 2012; Weston and Mathesius, 2013). Flavonoids have been shown to modulate auxin transport and seem to modulate the activity of regulatory proteins such as protein phosphatases and kinases (Gamet-Payrastré *et al.*, 1999; Peer and Murphy, 2007; Grunewald *et al.*, 2012; Weston and Mathesius, 2013). Anthocyanins are a class of water-soluble flavonoid pigments that can provide red to blue colours in flowers, fruits, leaves, and storage organs. Their occurrence in reproductive organs attracts pollinators and aids seed dispersal (Petroni and Tonelli, 2011). The accumulation of anthocyanin pigments in vegetative tissue can be induced by environmental stressors, such as high light, extreme temperatures, osmotic stress, salt stress, sucrose feeding, nutrient deficiency, mechanical damage, pathogen attack, pollution, and herbicides (Chalker-Scott, 1999; Winkel-Shirley, 2002; Gould, 2004, Azuma *et al.*, 2012). The presence of anthocyanins in leaves at particular stages of development, and their induction by a variety of environmental stressors is dependent on the highly coordinated transcriptional regulation of anthocyanin biosynthesis genes. This regulation is achieved through a set of specific transcription factors (TFs), including MYB, bHLH and WD-repeat proteins that form MBW complexes (de Vetten *et al.*, 1997; Walker *et al.*, 1999; Zhang *et al.*, 2003; Carey *et al.*, 2004; Morita *et al.*, 2006; Schwinn *et al.*, 2006). According to the current model for the activation of anthocyanin biosynthesis genes, these transcriptional regulators interact with each other and form complexes in conjunction with promoters of anthocyanin biosynthesis genes. For example, the MYB factor encoded by the

## 4. General Discussion and Outlook

---

*COLORLESS1 (C1)* gene from maize (*Zea mays*) interacts with bHLH factors B and R to activate the promoter of the *DIHYDROFLAVONOL-4-REDUCTASE (DFR)* gene (Chandler *et al.*, 1989; Ludwig *et al.*, 1989; Goff *et al.*, 1992). In *Arabidopsis* there are four MYB factors that interact within MBW complexes, including PAP1/MYB75, PAP2/MYB90, MYB114 and MYB113 (Walker *et al.*, 1999; Zhang *et al.*, 2003; Baudry *et al.*, 2006; Gonzalez *et al.*, 2008). A number of bHLH TFs can participate in this complex: Glabra 3 (GL3/bHLH001), Enhancer of Glabra 3 (EGL3/bHLH002) and TT8/bHLH042 (Zhang *et al.*, 2003; Baudry *et al.*, 2006; Gonzalez *et al.*, 2008). Resulting complexes regulate expression of anthocyanin biosynthesis genes such as *ANTHOCYANIDIN SYNTHASE (ANS)* or *DFR*. Interestingly, the *ttg1* mutant, as well as the double *gl3egl3* mutant show a pleiotropic phenotype, including defective anthocyanin production, trichome patterning, seed coat mucilage production, and position-dependent root hair spacing (Payne *et al.*, 2000; Bernhardt *et al.*, 2005; Bouyer *et al.*, 2008; Zhao *et al.*, 2008). Multiple experiments revealed that TTG1 and TT8 in complex with a MYB factor Transparent Testa 2 (TT2/MYB123) can form an additional MBW complex to specifically regulate anthocyanidin biosynthesis, providing substrate for epicatechin and proanthocyanidin in seeds and *ban* embryos (Nesi *et al.*, 2001; Baudry *et al.*, 2004; Lepieniec *et al.*, 2006). In addition, *Arabidopsis* Production of Flavonol Glycoside (PFG) factors from subgroup 7 of the R2R3-MYB family, namely MYB11/PFG2, MYB12/PFG1 and MYB111/PFG3 have been reported to control the flavonol branch of the flavonoid biosynthetic pathway by activating *CHS*, *CHI*, *F3H* and *FLAVONOL SYNTHASE (FLS)* (Mehrtens *et al.*, 2005; Stracke *et al.*, 2007).

Flavonoids accumulate in plant tissues in response to environmental inputs. Particularly well studied has been the effect of nutrient (mostly nitrogen) limitation on anthocyanin accumulation. Several early (*CHS*, *F3H*, *F3'H*) and late (*DFR*, *ANS*) flavonoid/anthocyanin biosynthesis genes have been reported to be induced by nitrogen and phosphorous depletion in a number of experiments, in *Arabidopsis* and other plant species (e.g. Scheible *et al.*, 2004; Misson *et al.*, 2005; Morcuende *et al.*, 2007; for a comprehensive review see Lillo *et al.*, 2008). Furthermore, many genes encoding enzymes known or predicted to be involved in biosynthesis or modification of flavanoids including various UDP-dependent glycosyl transferases (UGTs) were

## 4. General Discussion and Outlook

---

found to be (highly) induced by mineral nutrient depletion (Lillo *et al.*, 2008). In addition to nutrient limitation, light quantity and quality have been shown to strongly affect anthocyanin biosynthesis (Mancinelli, 1985; Wade *et al.*, 2001; Takos *et al.*, 2006; Cominelli *et al.*, 2008; Albert *et al.*, 2009; Stracke *et al.*, 2010; Azuma *et al.*, 2012). Similarly, several TFs controlling the expression of flavonoid biosynthesis genes in response to other environmental cues have been reported. In *Arabidopsis*, the Phytochrome-Interacting Transcription Factor3 (PIF3), a member of the bHLH protein family, acts as a positive regulator of anthocyanin biosynthesis (Shin *et al.*, 2007). The bZIP transcription factor Elongated Hypocotyl5 (HY5) plays a key role for light-dependent processes in plants and has been shown to positively regulate the expression of several flavonoid biosynthesis genes, including *CHS* and *F3H*, as well as the *MYB12/PFG1* transcription factor (Stracke *et al.*, 2010). Of note, *HY5* expression is not much altered by mineral depletion (reported in Lillo *et al.*, 2008), indicating the involvement of other TFs in the regulation of nitrogen and phosphorous deficiency-modulated expression of flavonoid biosynthesis genes. Indeed, both, *PAP1* and *PAP2* are induced by nitrogen and phosphorous depletion (Lillo *et al.*, 2008). *PAP1* has been shown to upregulate the expression of twenty flavonoid biosynthesis genes (Tohge *et al.*, 2005), and expression of almost all of these genes was also elevated by nitrogen and/or phosphorous limitation (see meta-analysis by Lillo *et al.*, 2008), indicating that PAP transcription factors play an important role in the mineral nutrition response of flavonoid/anthocyanin pathway genes. However, there are notable differences in the expression of *PAP1* and *PAP2* themselves. In several studies, *PAP2* expression was found to be more stimulated than *PAP1* expression under conditions of mineral nutrient deprivation (see for example Misson *et al.*, 2005; Lea *et al.*, 2007; Morcuende *et al.*, 2007), and *PAP1* acts in the sucrose-mediated up-regulation of flavonoid biosynthesis genes (Teng *et al.*, 2005; Solfanelli *et al.*, 2006). Of particular note, *PAP1* and *PAP2* are also upregulated by exposure of plants to light, a condition that also upregulates many flavonoid biosynthesis genes (Cominelli *et al.*, 2008). High light induces the expression of *MYB12/PFG1* and *MYB111/PFG3*, key regulators of the flavonol pathway; this induction correlates with the strong influence high light has on flavonol biosynthesis (Mehrtens *et al.*, 2005). The Glabra 3 (GL3/bHLH001) transcription factor interacts with *PAP1* and *PAP2* to activate the expression of the anthocyanin biosynthesis gene *DFR* (Zimmermann *et*

## 4. General Discussion and Outlook

---

*al.*, 2004b). Notably, expression of *GL3* increases upon nitrogen limitation. Given that the nitrogen depletion-triggered accumulation of anthocyanins, that is normally seen in wild-type plants, was absent in the *g/3* mutant, it was concluded that *GL3* is important for the nutrient deprivation response (Feyissa *et al.*, 2009). In addition, the negative regulator Caprice (*CPC*) was reported to repress anthocyanin accumulation under nitrogen limitation condition. Similarly, *CPC* represses anthocyanin accumulation in *35S* overexpressors grown under osmotic, salinity or cold stress, however, no difference was observed between wild-type and *cpc-1* mutant plants (Fig. 6 in Zhu *et al.*, 2009). Furthermore, *LBD37*, *LBD38*, and *LBD39*, members of the Lateral Organ Boundry Domain (*LBD*) transcription factor family, have been shown to negatively regulate nitrogen depletion-induced anthocyanin formation in *Arabidopsis*, possibly via repression of *PAP1* and *PAP2* (Rubin *et al.*, 2009). Salinity stress is yet another environmental factor known to trigger anthocyanin accumulation in a number of plant species. Eryilmaz (2006) reported that anthocyanin content was increased by nearly 73% in the cotyledons and 51% in the hypocotyls of tomato seedlings treated with 100 mM NaCl, compared to the control. Similarly, anthocyanin content in cotyledons and hypocotyls of salt-treated red cabbage seedlings increased by approximately 70% and 65%, respectively, in relation to the control. Kaliamoorthy and Rao (1994) reported an up to 40% increase in anthocyanin accumulation in maize as a salinity stress response. Salt-induced anthocyanin accumulation was also shown in sugarcane (Wahid and Ghazanfar, 2005). Salinity leads to water deficit and ionic stress resulting in the destabilization of membranes, inhibition of enzymes, and the overproduction of reactive oxygen species (*ROS*) (Zhu, 2001; Munns, 2002; Miller *et al.*, 2010), and the accumulation of anthocyanins has been proposed to contribute to plant tolerance against abiotic stresses (Gould *et al.*, 2002; Nagata *et al.*, 2003; Gould, 2004; Zeng *et al.*, 2010). Salt stress (especially when prolonged) can cause precocious senescence and result in e.g. chlorophyll loss. In conditions, when chlorophyll is being degraded plants become more susceptible to photoinhibition. It can be hypothesized that, as in the case of senescence, anthocyanins protect the photosynthetic apparatus of salt treated plants from damaging effects of high-energy radiation. We treated *Arabidopsis* wild-type seedlings with 100 mM NaCl solution for five days (**Figure 32**). Plants in medium

## 4. General Discussion and Outlook

containing salt (left panel), turned reddish, whereas control plants in MS medium remained green.

**Figure 32. Phenotype of wild-type *Arabidopsis* seedlings under salt stress.**

*Arabidopsis* seedlings were grown on solid MS medium supplemented with 1% sucrose. After two weeks, seedlings were transferred to a liquid MS medium with or without salt (100 mM NaCl). After five days, seedlings treated with salt started to accumulate anthocyanins (arrows and magnified picture)

In contrast to the regulation of anthocyanin biosynthesis under nutrient deprivation, the signaling cascade and involvement of TFs in salt-triggered accumulation of flavonoids/anthocyanins have rarely been investigated so far. Recently, constitutive overexpression of the *Arabidopsis* Shaggy-like Protein Kinase1 (GSK1) in transgenic plants was shown to induce salt stress responses, including the accumulation of

anthocyanins, concomitant with strongly increased *CHS* expression, in the absence of salinity stress (Piao *et al.*, 2001). In the wild type, *CHS* was highly induced by salt stress. These data led to the proposition that GSK1 plays an important role in the signaling cascade(s) that control activation of anthocyanin pathway genes upon exposure of plants to salt stress (Piao *et al.*, 2001). However, nothing is currently known concerning the effect of GSK1 overexpression on the expression of TFs regulating flavonoid/anthocyanin biosynthesis genes. Recently, *MYB44*, a member of subgroup 22 of the R2R3-MYB TF family, was shown to be activated by different abiotic stresses, including dehydration, low temperature and salinity (Jung *et al.*, 2008). After 24 hours of salinity stress, but not under control condition, the expression of *CHS*, *F3H*, *DFR*, *PAP1* and *PAP2* was decreased in transgenic plants overexpressing *MYB44* (Jung *et al.*, 2008). In addition, anthocyanin accumulation was less prominent in *35S:MYB44* seedlings than in wild-type plants, particularly following jasmonate treatment (Jung *et al.*, 2010). These data indicate a negative role of MYB44 in stress-induced anthocyanin accumulation. However, a direct regulation of flavonoid/anthocyanin pathway genes by MYB44 has not, as yet, been reported.

### 4.1. Model of MYB112 Action

We discovered MYB112 as a novel transcriptional regulator of flavonoid biosynthesis in *Arabidopsis thaliana*. Based on our experimental data, we propose a model (**Figure 33**) in which MYB112 acts as a positive regulator of anthocyanin biosynthesis and a negative regulator of flavonol biosynthesis. As we demonstrate, MYB112 activates *PAP1* and *MYB114*, but inhibits *MYB12* and *MYB111*. *PAP1* and *MYB114* regulate the expression of genes encoding enzymes involved in anthocyanin formation (for example *ANS* and *DFR*) and expression of these genes is increased upon *MYB112* induction. However, it needs to be stressed that only the Landsberg erecta (Ler) *MYB114* allele, and not the Columbia (Col) allele, was functionally characterised. MYB111 and MYB12 control expression of genes involved in flavonol biosynthesis (for example *CHS* and *FLS*) and their transcript levels are decreased in *MYB112-IOE* plants after estradiol treatment. We did not obtain evidence for a direct regulation of either the known anthocyanin or flavonol biosynthesis genes or their regulators. At the current stage of analysis it thus remains

## 4. General Discussion and Outlook

---

open how the regulation of the flavonoid pathway by MYB112 is achieved. However, one possible scenario is that this regulation occurs through the direct activation of *MYB32* and *MYB7* by MYB112. *MYB32* and *MYB7*, as well as MYB112 early responsive gene *MYB6*, classify to the subgroup 4 of R2R3-MYB factors. Subgroup 4 of R2R3-MYB factors is characterized by the two motifs representing a putative activation domain LlsrGIDPxT/SHRxI/L at the end of the R3 repeat of the DNA binding domain and a putative negative regulatory domain pdLHLD/ELxiG/S in the C-termini (Jin *et al.*, 2000). *MYB32* was previously shown to affect expression of flavonoid/phenylpropanoid biosynthesis pathway genes and to affect pollen development. Disruption of *MYB32* by T-DNA insertion leads to the formation of aberrant pollen. A similar phenotype is observed when the closely related *MYB4* gene is mutated or overexpressed. It was speculated that changes in the expression of flavonoid and phenylpropanoid biosynthesis genes influence the flux along these pathways, interfering with pollen development by altering structural components of the pollen wall, such as sporopollenin (Preston *et al.*, 2004). Our results reported here indicate that overexpression of *MYB112* also leads to partial pollen sterility. Expression profiling in the *myb112-1* mutant and the *MYB112-IOE* plants treated with estradiol for 5 days revealed significant changes in the expression of a number of phenylpropanoid biosynthesis genes in *MYB112* transgenic plants. *MYB32*, *MYB7* and *MYB4* were recently reported to be direct downstream target genes of MYB46 and MYB83. These two TFs recognize the 7-bp consensus sequence ACC(A/T)A(A/C)(T/C) (Zhong and Ye, 2012; Kim *et al.*, 2012), which is highly similar to the MYB112 binding site reported here: (A/T/G)ACC(A/T)(A/G)(A/C)(T/C). MYB46 and MYB83 function redundantly to control the production of all major secondary cell wall components in *Arabidopsis* fibers and vessels, such as lignin, cellulose and xylan (Ko *et al.*, 2009; Zhong and Ye, 2012). MYB58 and MYB63 are yet another MYB factors involved in controlling the formation of the secondary cell wall. Contrary to MYB46 and MYB83, they are specifically involved in the regulation of lignin biosynthesis (Zhou *et al.*, 2009). Their overexpression was found to induce ectopic deposition of lignin but not cellulose and xylan, whereas their dominant repression resulted in a reduction of secondary wall thickening. In this network, expression of *MYB46/83* and *MYB58/63* is under the control of the Secondary Wall-associated NAC Domain Protein1 (SND1) and its close homologs, NST1, NST2, VND6 and

## 4. General Discussion and Outlook

---

VND7 (Zhong and Ye, 2009; Zhou *et al.*, 2009; Zhong *et al.*, 2010). Zhong and Ye (2012) suggest that *MYB32*, *MYB7* and *MYB4* may be involved in fine-tuning the regulation of lignin biosynthesis during secondary wall deposition. Based on microarray experiments, expression of *MYB112* is neither affected by overexpression of the secondary wall NACs (SWNs; Zhong *et al.*, 2010) nor *MYB46/83* (Ko *et al.*, 2009), and *GUS* promoter activity assays revealed that *MYB112* is mainly expressed in leaves and pollen, while SWNs and *MYB46/83* factors are expressed in vascular tissue. It may, however, be that *MYB112* acts as a SWN-independent regulator of lignin biosynthesis, or of the biosynthesis of other phenylpropanoids, leading to the observed pollen phenotype. Further functional characterization of *MYB7* and *MYB32*, as well as the identification of direct target genes of both TFs will be necessary to refine the *MYB112* regulatory network.

From our studies, we can confirm, that expression of *MYB112* increases during senescence, as well as upon salt and high light stress; conditions in which plants often receive more light energy than can be used for photochemical reactions. Excess light energy leads to photoinhibition and the formation of reactive oxygen species (ROS). Anthocyanins absorb excess quanta, thereby protecting plant tissue from damaging light levels. Accumulation of anthocyanins has been reported to occur under salinity conditions in a number of species including crops and vegetables, such as tomato, maize, sugarcane and many others (see for example Kaliamoorthy and Rao, 1994; Piao *et al.*, 2001; Wahid and Ghazanfar, 2006; Keutgen and Pawelzik, 2007; Roychoudhury *et al.*, 2008; Matus *et al.*, 2010). However, although salinity stress is well known to lead to an accumulation of anthocyanin, the regulatory mechanisms underlying this phenomena have not been studied intensively to date. Herein, we show that *MYB112* expression is induced by salinity stress, whilst its expression is largely unaffected by nitrogen limitation, and sugar levels, in contrast to many of the known transcriptional regulators of flavonoid/anthocyanin biosynthesis (Scheible *et al.*, 2004; Misson *et al.*, 2005; Lea *et al.*, 2007; Morcuende *et al.*, 2007; Lillo *et al.*, 2008).

**Figure 33. Model of MYB112 action.**

MYB112 acts as a positive regulator of *PAP1* and *MYB114*, but inhibits *MYB12* and *MYB111*. *PAP1* and *MYB114* (in Ler background) regulate the expression of genes encoding enzymes involved in anthocyanin formation (e.g., *ANS* and *DFR*), and *MYB111* and *MYB12* control expression of genes involved in flavonol biosynthesis (e.g., *CHS* and *FLS*). We propose this regulation to occur through the direct activation of *MYB32* and *MYB7* expression by MYB112. MYB32 was shown to affect expression of flavonoid biosynthesis pathway genes as well as pollen development. Expression of *MYB112* increases during senescence, as well as during salt and high light stress. High light activation of *MYB112* expression can be regulated through TSP9 signaling. In the absence of functional TSP9, high light-induced *MYB112* expression is abolished (Fristedt *et al.*, 2009). Expression of *MYB112* is negatively regulated by MYB44 under conditions of salt stress (Jung *et al.*, 2008). MYB112 also affects bolting time; a similar phenotype is observed for MYB44 overexpression plants.

## 4. General Discussion and Outlook

---

We further illustrate that salinity-induced accumulation of anthocyanin is impaired in *myb112* mutants, but stimulated in *35S:MYB112* overexpressors, indicating that MYB112 plays a critical role during salt-induced anthocyanin accumulation. In addition, light quantity and quality have been shown to strongly affect anthocyanin biosynthesis (Mancinelli, 1985; Wade *et al.*, 2001; Takos *et al.*, 2006; Cominelli *et al.*, 2008; Albert *et al.*, 2009; Stracke *et al.*, 2010; Azuma *et al.*, 2012). Here, we report that *myb112-1* mutant accumulates less anthocyanins when subjected to high light stress ( $500 \mu\text{mol m}^{-2} \text{s}^{-1}$ ) for three days, suggesting that MYB112 is involved in high light-induced anthocyanin accumulation. High light activation of MYB112 expression may be regulated through TSP9 signaling. TSP9 is a thylakoid-anchored protein, which under high light is phosphorylated and partially released from the membrane. In the absence of functional TSP9, high light-induced MYB112 expression is abolished (Fristedt *et al.*, 2009). Further studies will, however, be required to reveal the details about the signalling pathways that control MYB112 expression during salinity and high light stress. It would be interesting to investigate the fitness of both *myb112* mutant and MYB112 overexpression plants under these two stress conditions by monitoring chlorophyll and flavonoid/anthocyanin content, SAGs expression, as well as photosynthesis parameters, such as non-photochemical quenching and chlorophyll fluorescence. If anthocyanins protect plants from excessive light, then we should see a difference in photosynthesis parameters when comparing wild-type plants with *myb112* T-DNA mutant, that accumulates less anthocyanin under salinity and high light conditions. Anthocyanins also act as scavengers of ROS. Diaminobenzidine (DAB; Fryer *et al.*, 2002) staining of *myb112* mutant as well as *35S:MYB112* and MYB112-IOE plants treated with estradiol could give an initial idea about H<sub>2</sub>O<sub>2</sub> accumulation in these plants compared to respective controls.

Published literature indicates that the expression of MYB112 is negatively regulated under conditions of salt stress, by MYB44, a member of subgroup 22 of the R2R3-MYB TF family (Jung *et al.*, 2008). Notably, expression of MYB32 and MYB7, the two direct targets of MYB112, was also decreased in MYB44 overexpression plants upon salt stress (Jung *et al.*, 2008). In addition, expression levels of flavonoid/anthocyanin biosynthesis genes, such as *CHS*, *F3H*, *ANS*, *DFR*, *PAP1* and *PAP2*, were

## 4. General Discussion and Outlook

---

decreased in *35S:MYB44* plants under salinity conditions (Jung *et al.*, 2008; E-ATMX-30). Subsequent studies have revealed that *MYB44* overexpressing seedlings accumulate less anthocyanin than wild-type plants, while *myb44* knockout plants show elevated levels of anthocyanin (Jung *et al.*, 2010). Described phenotype of *MYB44* transgenic seedlings is opposite to that of *MYB112* transgenics (see **Figure 19** and **20**). Moreover, bolting time is affected in *35S:MYB44* plants. Wild-type plants bolt earlier than *35S:MYB44* overexpressors (Jung *et al.*, 2008), what is also evident in *myb112* T-DNA mutant and *MYB112* RNAi plants analysed here (see **Figure 29** and **30**). To verify the model that *MYB44* acts as a direct or indirect negative regulator of *MYB112*, we generated estradiol-inducible *MYB44* overexpression (*MYB44-IOE*) plants and treated transgenic seedlings with estradiol in the absence of salt stress, and then induced salt stress (150 mM NaCl) (in presence of estradiol). Using qRT-PCR we detected decreased *MYB112* expression in two out of four tested lines (**Figure 31**), indicating that the regulation of *MYB112* expression by *MYB44* may be indirect and may require additional factors, modulating this regulation.

*MYB112* also functions as a regulator of plant development and *MYB112*-deficient plants exhibit delayed bolting. It is still unknown which physiological cues determine this phenotype but interestingly a similar phenotype was observed for *MYB44* overexpressing plants (Jung *et al.*, 2008). The bolting phenotype can be related with the fact that certain flavonoids modulate auxin signalling in plants (Jacobs and Rubery, 1988; Kuhn *et al.*, 2011). Flavonoids have been considered natural regulators of cellular auxin efflux and consequent polar auxin transport since Jacobs and Rubery (1988) reported that flavonoid compounds displace the auxin efflux inhibitor 1-naphthylphthalamic acid (NPA) from zucchini (*Cucurbita pepo*) hypocotyl microsomes. Brown *et al.* (2001) observed that plants with a mutation in the gene encoding the first enzyme in flavonoid biosynthesis - *CHS* (*tt4* mutants) display decreased flavonoid accumulation and reduced height in comparison to wild-type plants. The *tt4* phenotype is correlated with enhanced auxin transport from shoot tip to root tip in the absence of flavonoids. Additionally, according to Peer *et al.* (2004) in the presence of excess kaempferol and quercetin in *F3'H* mutant (*tt7*) and *DFR* mutant (*tt3*), basipetal auxin transport is reduced. Later studies have reaffirmed the link between flavonoids and plant architecture by showing that flavonoid-defective

mutants display a wide range of alterations to root and shoot development (Taylor and Grotewold, 2005; Peer and Murphy, 2007; Besseau *et al.*, 2007; Buer and Djordjevic, 2009). Further investigations, including auxin transport measurements, are necessary to clarify if the delayed bolting of *myb112* mutants is caused by an increased basipetal auxin transport.

### 4.2. Integration of Methods for Functional Characterisation of TFs

The functional characterization of a TF is not a trivial task. Due to the dynamic nature of developmental and environmental responses, transcriptional networks are highly complex. Refinement of the existing methods in combination with emerging approaches will most likely contribute to the progress in our understanding of transcriptional regulation. Commonly used phenotype analysis of gain- and loss-of-function mutants often provides a good biological insight into a TF function but does not allow identifying its downstream targets and gene expression networks controlled by the TF of interest. In order to identify TF-responsive genes we used an inducible overexpression system. Compared to constitutive promoters, inducible promoters offer numerous advantages, namely a transgene can be expressed at a given developmental stage for a specific duration of time. It also gives the opportunity to overexpress a transgene, whose constitutive overexpression is detrimental to the host plant. One of the commonly used inducible systems utilises a fusion between the TF of interest and a steroid-binding domain. In the absence of the inducer, the fusion protein is localised in the cytoplasm and therefore inactive (Lloyd *et al.*, 1994). Upon addition of a steroid, for example dexamethasone (DEX), conformational changes in the steroid-binding domain result in nuclear targeting of the fusion protein and in consequence activation of the TF (Lloyd *et al.*, 1994), whereas the expression level of the chimeric gene itself remains unchanged. One advantage of this system, besides its simplicity, is that direct and indirect effects of TF activity may be separated by using inhibitors of protein synthesis (such as cycloheximide). However, cycloheximide treatment itself causes thousands of expression changes (data from AtGeneExpress Chemical Series by Vinegar and Winter, 2004) and so it is not often used. Therefore, a typical experimental setup involves induction, preferably at the developmental stage that TF is biologically relevant, followed by harvesting and

## 4. General Discussion and Outlook

---

expression analysis at different times following induction. It is also crucial to use appropriate controls in order to exclude that the changes are caused by application of a steroid (or protein synthesis inhibitor, if used). Other commonly used inducible systems are not restricted to nuclear proteins and rely on transcriptional regulation (Zuo and Chua, 2000; Padidam, 2003). Some of these systems use a chimeric TF, that when induced migrates to the nucleus activating transcription of the gene/TF of interest, whilst others utilise 'stimulus' activated promoters. The inducers range from hormones (estradiol) and chemicals (ethanol) to stress stimuli such as wounding or heat. In our study we used an estradiol (EST)-inducible system. In this system, the gene/TF of interest is cloned downstream of a promoter targeted by the synthetic XVE transcription factor (Zuo *et al.*, 2000). XVE is comprised of the *E. coli* *lexA* repressor domain fused to the VP16 transactivation domain and the regulatory region of the human estrogen receptor. In the presence of estrogens such as  $\beta$ -estradiol or 4-hydroxyl tamoxifen, XVE binds to eight copies of the *lexA* operator fused upstream of the 35S minimal promoter ( $O_{lexA-46}$ ) and activates transcription (Zuo *et al.*, 2000). The XVE transcription factor is expressed from the strong synthetic promoter G10-90 that exhibits eightfold higher activity than CaMV 35S (Ishige *et al.*, 1999). The vector pER8 carries the G10-90::XVE cassette on the same T-DNA as the  $O_{lexA-46}$  promoter.

Short time activation of a TF using an inducible system, followed by genome-wide expression profiling (e.g. microarray ATH1 or RNAseq), facilitates identification of its early responsive genes and is a good starting point towards the identification of direct targets. Microarray results should be further verified using more sensitive qRT-PCR and transactivation assays. In order to fish the direct target genes out of the set of TF early responsive genes a combination of methods is necessary. As TFs exert their function by binding to specific DNA sequences, methods aiming at the identification of the TF binding site (BS) represent a crucial first step towards deciphering direct target genes. The most commonly used BS selection methods are based on SELEX (Systematic Evolution of Ligands by EXponential enrichment), which uses a purified TF protein to enrich short nucleotide sequences that bind tightly to it from a large initial pool of random synthetic DNA fragments (see Chai *et al.*, 2011). After several rounds of selection the nucleotide sequences of the tightly bound DNAs are determined and a consensus DNA recognition sequence is formulated. In our study

## 4. General Discussion and Outlook

---

we used the CELD method developed by Gang-Ping Xue (CSIRO Plant Industry, Brisbane, Australia). Binding of the TF to the identified consensus DNA sequence may subsequently be confirmed by electrophoretic-mobility shift assay (EMSA). EMSA relies on a difference in the mobility between free and protein bound DNA fragments during gel electrophoresis. The exact sequence requirements for the bound motif can be further investigated by the mutation of individual nucleotides and using these modified sequences to compete for the binding of the TF protein. Besides EMSA, several protocols describe the effective use of an ELISA-based transcription factor binding assay e.g. for the analysis of human NFκB binding to specific DNA sequences. In plants, DNA-Protein Interaction (DPI)-ELISA was established and used for qualitative analyses with HIS-tagged TFs expressed in *E. coli*. Studies confirmed that EMSA and DPI-ELISA result in comparable data, as the binding of *AtbZIP63* to the C-box and *AtWRKY11* to the W2-box could be reproduced and validated by both methods (Brand *et al.*, 2010). Recent progress in genome-wide *in vivo* techniques, like DNA adenine methyltransferase identification (DamID), or chromatin immunoprecipitation followed by high-throughput sequencing (ChIP-seq) or DNA microarray analysis (ChIP-chip) enables plant researchers to generate genome-wide, high-resolution DNA-binding maps of transcription factors. ChIP-qPCR on the other hand can be used to confirm that the binding between a TF and an *in vitro* identified BS, occurs also *in vivo*. FAIRE (Formaldehyde Assisted Isolation of Regulatory Elements) is yet another method used to identify transcriptionally active DNA regions, following a stimuli (e. g. TF activation, stress treatment). In the active state, chromatin shows a temporary displacement of nucleosomes, favoring the interaction of DNA-binding proteins with the genomic regulatory elements (Nagy *et al.*, 2003; Giresi *et al.*, 2007; Giresi and Lieb, 2009). In FAIRE, the total chromatin is crosslinked by formaldehyde and fragmented by sonication followed by phenol:chloroform DNA extraction. In result, the nucleosome depleted fragments of DNA are isolated from the fragments containing high levels of crosslinked proteins. For the genome-wide identification of nucleosome-depleted regions (putative regulatory elements), the DNA fragments present in the FAIRE samples are sequenced by deep sequencing technology.

Whole genome sequencing, the relative ease of transcript profiling by the use of microarrays and qRT-PCR, as well as prompt development of methods leading to

## *4. General Discussion and Outlook*

---

identification of TF binding sites (SELEX, ChIP, etc.) have facilitated the capture of vast amounts of transcript data and gene-to-gene networks.

The metabolome is the final product of a series of gene actions. Hence, metabolomics has a potential to elucidate gene functions, especially when integrated with transcriptomics.

In the present study, we could find gene-to-gene and metabolite-to-gene networks and could identify a new gene function through integrated analysis of metabolomics and transcriptomics.

### 5. Materials and Methods

#### General

Standard molecular techniques were performed as described (Sambrook et al., 2001; Skiryecz et al., 2008). Primer sequences are given in **Supplementary Table 1**. For gene expression analyses the online tools of Genevestigator (<http://www.genevestigator.com>; Zimmermann et al., 2004a) and eFP browser (<http://www.bar.utoronto.ca/efp/cgi-bin/efpWeb.cgi>; Winter et al., 2007) were used.

#### Plants

Seeds of *Arabidopsis thaliana* (L.) Heynh. ecotype Col-0 were obtained from the *Arabidopsis thaliana* Resource Centre for Genomics (Institut National de la Recherche Agronomique, France; <http://dbsgap.versailles.inra.fr/publiclines>). *Arabidopsis thaliana* seedlings were grown on selection plates in a climate chamber with a 16-h day length provided by fluorescent light at 30  $\mu\text{mol m}^{-2} \text{s}^{-1}$  and a temperature of 22°C. After two weeks plants were transferred to the soil (Einheitserde GS90; Gebrüder Patzer) and grown under controlled conditions in a greenhouse at 16-h day length (120  $\mu\text{mol m}^{-2} \text{s}^{-1}$ ) and a day/night temperature of 21/18°C and relative humidity (RH) 60/75%. The T-DNA insertion lines originated from the SALK collection and GABI-KAT (SALK\_098029, GK\_093E05).

#### Constructs

*Pro<sub>MYB112</sub>:GUS*: A ~1.3-kb fragment upstream of the *MYB112* gene was amplified from genomic *Arabidopsis thaliana* Col-0 DNA by PCR using primers MYB112:GUS-fwd. and MYB112:nested-rev., inserted into plasmid pCR2.1 (Invitrogen, Karlsruhe, Germany) and used as a template for PCR-amplification of the ~1.3-kb region upstream of the translation initiation codon using primers MYB112:GUS-fwd. and MYB112:GUS-rev. The ~1.3-kb promoter was fused via EcoRI and NcoI sites to the  $\beta$ -glucuronidase (*GUS*) reporter gene in pCAMBIA1305.1-Hygromycin (CAMBIA, Canberra, Australia). *35S:MYB112*: MYB112 open reading frame, amplified by PCR from *Arabidopsis* cDNA using primers MYB112-OE-fwd. and MYB112-OE-rev., was inserted into pCR2.1 (Invitrogen) and then cloned via added HindIII sites into a CaMV

35S promoter-containing pGreen0029 vector (Skirycz et al., 2006). *35S:MYB112-GFP*: *MYB112* coding sequence was amplified by PCR from *Arabidopsis* cDNA using primers MYB112-fwd. and MYB112-rev. and inserted into pDONR201 vector (GATEWAY, Invitrogen). Subsequently, the fragment was cloned into the GATEWAY-compatible vector pK7FWG2.0 (Ghent University) using LR reaction. *MYB112-IOE*: *MYB112* coding region was amplified by PCR from *Arabidopsis* leaf cDNA using primers MYB112-IOE-fwd. and MYB112-IOE-rev., inserted into pCR2.1 and then cloned via XhoI and SpeI sites into pER8 vector (Zuo et al., 2000). *Agrobacterium tumefaciens* strain GV3101 (pMP90) was used for *Arabidopsis thaliana* (Col-0) transformations. *MYB44-IOE*: *MYB44* coding region was amplified by PCR from *Arabidopsis* leaf cDNA using primers MYB44-IOE-fwd. and MYB44-IOE-rev., inserted into pCR2.1 and then cloned via XhoI and SpeI sites into pER8 vector (Zuo et al., 2000). *Agrobacterium tumefaciens* strain GV3101 (pMP90) was used for *Arabidopsis thaliana* (Col-0) transformations. *Pro::fLUC* fusions: ~1.7-kb fragments upstream of the respective gene coding sequences from the genes *MYB6*, *MYB7* and *MYB32* were amplified using PCR from *Arabidopsis* genomic DNA, ligated into the pENTR/D-TOPO vector (Invitrogen) and subsequently recombined into the GATEWAY-compatible vector pGW7 (Licausi et al., 2011). *Tac:MYB112-CELD-HIS*: *MYB112* coding sequence was amplified using MYB112-CELD-fwd. and MYB112-CELD-rev. and cloned to the pTacLCELD6xHIS (Xue, 2002; Xue, 2005) vector via NheI and BamHI restriction sites.

### Isolation of *myb112* T-DNA Insertion and RNAi Lines

T-DNA insertion lines in Col-0 background were obtained from either the SALK (SALK\_098029, *myb112-2*) or GABI-Kat (GK\_093E05, *myb112-1*) collections. Homozygous plants were identified by PCR using the following primers: for SALK\_098029, T-DNA left border primer LB, gene-specific primers SALK\_LP and SALK\_RP; for GK\_093E05, T-DNA left border primer LB, gene-specific primers GK\_LP and GK\_RP. *MYB112* expression in the T-DNA insertion plants was examined by qRT-PCR using gene-specific primers and by end-point PCR using primers annealing to the 5' and 3' ends of the *MYB112* coding region. RNAi lines were obtained from AGRIKOLA (<http://www.agrikola.org>).

### **Estradiol Induction Experiments**

*Arabidopsis* seedlings transformed with the *MYB112-IOE* construct were grown on solid MS medium supplemented with 1% sucrose and after two weeks were transferred into liquid MS medium supplemented with 10  $\mu$ M estradiol (EST) for the indicated times. As controls, DMSO-treated *MYB112-IOE* lines or EST-treated empty-vector (EV) plants were used.

### **RNA Isolation and cDNA Synthesis**

Total RNA extraction, cDNA synthesis and qRT-PCR were done as described (Caldana et al., 2007; Balazadeh et al., 2008b; Wu et al., 2012). After grinding plant material in liquid nitrogen, total RNA was isolated with Trizol reagent (Invitrogen) following the manufacturer's specifications. RNA quality was determined photometrically. RNA integrity was checked on 1% (w / v) agarose formaldehyde gels. 50  $\mu$ g of total RNA were treated with Turbo DNA-free recombinant DNase I (Applied Biosystems Applera, Darmstadt, Germany) to remove genomic DNA contamination. RNA integrity was checked again after digestion, and the absence of genomic DNA was verified by real-time PCR using primers for a genomic sequence (*UBQ10*). Two  $\mu$ g of total RNA was used in 20  $\mu$ L reactions for cDNA synthesis, using RevertAid R-minus cDNA synthesis kit (Fermentas, St. Leon-Rot, Germany). The cDNA was then diluted 1:10 in order to reduce the effect of RNA isolation and cDNA synthesis buffer on the subsequent PCRs.

### **Expression Profiling by qRT-PCR**

Total RNA extraction, cDNA synthesis and qRT-PCR were done as described (Caldana et al., 2007; Balazadeh et al., 2008b; Wu et al., 2012). PCR reactions were run on an ABI PRISM 7900HT sequence detection system (Applied Biosystems Applera, Darmstadt, Germany). Gene expression was analysed using the comparative Ct method. PCR reactions were carried out in technical triplicates using 0.5  $\mu$ L of diluted cDNA in 5  $\mu$ L reactions, 2  $\mu$ L of each 500 nM primer and 2.5  $\mu$ L of 2x Power SYBR Green PCR Master Mix (Applied Biosystems Applera). Assays were run using the thermal profile: 50 °C for 2 min; 95 °C for 10 min; 40 cycles of 95 °C for 50 s and 60 °C for 1 min. The primers used to test gene expression are shown in

**Supplementary Table 3.** Experiments were performed using three biological replicates.

### Microarray Experiments

Affymetrix ATH1 hybridisations were performed by ATLAS Biolabs (Berlin, Germany). Expression of *MYB112* was induced by 10  $\mu$ M estradiol in two-week-old seedlings grown on a rotary shaker in liquid MS medium at continuous light, identically treated empty-vector (pER8) transformed seedlings and seedlings treated with DMSO served as controls. Seedlings were harvested after various induction times (1 h, 3 h and 5 h) and RNA extracted from shoots was used for expression profiling.

### Reporter Transactivation Assay in Protoplasts

Protoplasts were isolated from *Arabidopsis* (Col-0) plants as described by Yoo et al. (2007) and transformed with *35S:MYB112* effector construct together with *ProMYB32::fLUC*, *ProMYB7::fLUC*, or *ProMYB6::fLUC* and *ProMYB7::fLUC* reporter constructs using 6  $\mu$ g plasmid DNA each. For normalization of the signal, protoplasts were simultaneously transfected with 6  $\mu$ g of *35S::rLUC* plasmid. Dual luciferase reporter assays were performed using the kit provided by Promega and luminescence was read using a GloMax 20/20 Luminometer (Promega). Experiments were performed using five biological replicates.

### DNA Binding Site Selection

#### a. Selection of cellulase-positive clones and purification of MYB112-CELD-HIS fusion protein.

The *Tac:MYB112-CELD-HIS* construct was transformed to *E. coli* XL1-Blue cells. The recombinant *E. coli* cells were screened for cellulase-positive clones by plating transformed cells on Luria Broth (LB)/ampicillin plates containing 0.2% (w/v) carboxymethyl-cellulose (CM-cellulose) substrate. After overnight incubation (12-20h, depending on expression level) at 37°C, the CM-cellulose plates were stained with 0.5% (w/v) Congo Red solution for 10 min at room temperature and destained by washing twice with 1 M NaCl (2 min for the first washing and 10-20 min for the second washing). Afterwards, MYB112-CELD-HIS fusion protein was purified from

cellulase-positive clones. Protein expression was induced using 1mM IPTG and cells were harvested 3 h after induction. Protein purification was performed under native conditions using Ni<sup>2+</sup>-agarose according to the Qiagen protocol (Qiagen, Hilden, Germany). Protein concentrations were determined by Bradford assay (Promega).

### **b. MYB112 binding site selection**

This work was performed in collaboration with Dr. G-P. Xue, CSIRO Plant Industry, Brisbane, Australia, according to Xue et al. (2005). Binding site selection was performed using the CELD system (Xue, 2005; Balazadeh et al., 2011) with *Tac:MYB112-CELD-HIS* construct, employing biotin-labeled double-stranded oligonucleotides containing a central 30-nt random sequence. MYB112-selected oligonucleotides were cloned. The cloned oligonucleotides were verified for the presence of MYB112 binding motif by DNA-binding activity assays and sequenced.

### **Electrophoretic Mobility Shift Assay (EMSA)**

MYB112-CELD-HIS fusion protein was purified from *E. coli* expression strain. Cells were sonicated in lysis buffer (50 mM Tris-Cl buffer, pH 7.3, 150 mM NaCl, 1 mM ethylenediaminetetraacetic acid (EDTA), 1 mM dithiothreitol (DTT), 1 mM phenylmethanesulfonyl fluoride (PMSF). Supernatant of centrifuged sample was used for purification using a 1-ml nickel column (GE Healthcare, Munich, Germany) coupled to an Äkta-Purifier FPLC system (GE Healthcare). Aliquots of the flow through fractions were analysed by SDS-PAGE and Coomassie staining. One-ml elution fractions containing the purified MYB112-CELD-HIS fusion protein were pooled and dialyzed against PBS buffer (20 mM Na-phosphate, pH 7.4, 150 mM NaCl). Protein concentration was determined by Bradford assay (Bradford, 1976). 5'-DY682-labeled DNA fragments were obtained from MWG (Ebersberg, Germany). Sequences of labeled DNA fragments and unlabeled competitors are given in **Supplementary Table 1**. Annealing was performed by heating the primers to 100°C followed by slow cooling to room temperature. Binding reaction was performed at room temperature for 20 min as described in the Odyssey Infrared EMSA kit instruction manual. DNA-protein complexes were separated on 6% retardation gel whilst DY682 signal was detected using the Odyssey Infrared Imaging System from LI-COR Biosciences (Bad Hamburg, Germany).

### Chromatin Immunoprecipitation coupled to qPCR (ChIP-qPCR)

To investigate *in vivo* binding of MYB112 to its DNA binding site in the promoter of *MYB32*, *MYB7*, *MYB6* and *UGT84A2*, we used ChIP-qPCR, using whole shoots from long day-grown, two-week-old *Arabidopsis* plants expressing GFP-tagged MYB112 protein from the CaMV 35S promoter (*35S:MYB112-GFP*). Wild-type plants were used as negative control. For the ChIP, we followed a protocol previously described by Kaufmann et al., 2010 employing anti-GFP antibody to immunoprecipitate protein-DNA complexes. The ChIP experiment was run in three independent replications. qPCR was used to test binding of MYB112 to its binding site within the selected promoters; the primers flanked the MYB112 binding site. As a negative control, we used primers annealing to promoter regions of two other *Arabidopsis* genes (*At3g18040* and *At2g22180*) lacking a MYB112 binding site. Primer sequences are given in **Supplementary Table 3**. We analysed ChIP-qPCR data relative to input, as this includes normalization for both background levels and input chromatin going into the ChIP. The amount of genomic DNA coprecipitated by GFP antibody (ChIP signal) was calculated in comparison to the total input DNA used for each immunoprecipitation in the following way: cycle threshold (CT) = CT(ChIP) – CT(Input). To calculate fold enrichment, normalized ChIP signals were compared between *35S:MYB112-GFP* and wild-type plants, where the ChIP signal is given as the fold increase in signal relative to the background signal. Experiments were performed in three biological replicates.

### Secondary Metabolite Profiling by LC-MS

Secondary metabolite analysis by LC-MS was performed as described by Tohge and Fernie (2010). All data were processed using Xcalibur 2.1 software (Thermo Fisher Scientific). The obtained data matrix was normalized using an internal standard Isovotexin; CAS 29702-25-8). Metabolites were identified and annotated based on comparisons with data in our previous publications (Tohge et al., 2005, 2007; Hirai et al., 2007; Yonekura-Sakakibara et al., 2008), metabolite databases (reviewed in Tohge and Fernie, 2009), and standard compounds (Yonekura-Sakakibara et al., 2008; Nakabayashi et al., 2009).

### **Microscopy**

We analysed the distribution of MYB112-GFP fusion protein by confocal fluorescence microscopy (Eclipse E600 microscope, Nikon, Düsseldorf, Germany).

### **Other Methods**

Histochemical GUS assays was performed as described by Plesch *et al.* (2001). Pollen viability was analysed using stereomicroscope MZ 12.5 (Leica) after Alexander staining (Alexander, 1969).

### **Statistical Analyses**

Unless otherwise specified, statistical analyses were performed using Student's t test embedded in the Microsoft Excel software. Only the return of  $p < 0.05$  was designated as statistically significant.

## Deutsche Zusammenfassung

Transkriptionsfaktoren (TFs) sind ubiquitäre Regulatoren der Genexpression und spielen eine essentielle Rolle in nahezu allen biologischen Prozessen. Diese Doktorarbeit hat vor allem die funktionelle Charakterisierung von *MYB112* zum Thema, einem Mitglied der R2R3-MYB-TF-Familie aus der Modellpflanze *Arabidopsis thaliana*. Ausgesucht wurde das Gen aufgrund seiner erhöhten Expression in seneszenten Blättern, basierend auf vorangegangenen qRT-PCR Expressionsprofilierungsexperimenten für 1880 TFs in *Arabidopsis* Blättern. *MYB112*-Promotor-GUS-Fusionslinien wurden generiert, um das Expressionsmuster von *MYB112* detailliert zu untersuchen. Unter Zuhilfenahme transgener Ansätze in Kombination mit *Metabolomics* und *Transcriptomics* können wir zeigen, dass *MYB112* eine wichtige Rolle in der Regulation des pflanzlichen Flavonoid-Metabolismus spielt. In *MYB112* Überexpressoren und *MYB112*-defizienten Mutanten kommt es zu erhöhter bzw. verminderter Anthocyanin-Akkumulation. Expressions-Profiling zeigt, dass *MYB112* einerseits als ein positiver Regulator des Transkriptionsfaktors *PAP1* fungiert, was zu einer erhöhten Anthocyanin-Biosynthese führt, andererseits als negativer Regulator von *MYB12* und *MYB111* auftritt, welche beide die Flavonol-Biosynthese kontrollieren. Wir haben früh auf *MYB112* reagierende Gene durch eine Kombination verschiedener Ansätze identifiziert. Diese umfassen Genexpressionsprofilierungs- (Affymetrix ATH1 Microarrays und qRT-PCR) und Transaktivierungs-Experimente in Mesophyll-Protoplasten aus Blättern. Wir zeigen, dass *MYB112* an ein 8-bp DNA-Fragment, welches die Kernsequenz (A/T/G)(A/C)CC(A/T)(A/G/T)(A/C)(T/C) aufweist, bindet. Mit Hilfe von *Electrophoretic Mobility Shift Assay* (EMSA) und Chromatin-Immunopräzipitation gekoppelt mit qPCR (ChIP-qPCR) zeigen wir, dass *MYB112* *in vitro* und *in vivo* an die Promotoren von *MYB7* und *MYB32* bindet, was sie damit als direkte Zielgene von *MYB112* identifiziert. Es wurde bereits gezeigt, dass MYB TFs eine wichtige Rolle bei der Kontrolle der Flavonoid-Biosynthese in Pflanzen haben. Viele Faktoren, die oberhalb des Anthocyanin-Biosyntheseweges agieren, werden bei Stickstofflimitierung oder erhöhter Saccharose-Konzentration auch verstärkt exprimiert. Außer den erwähnten Bedingungen können auch andere Umweltparameter, wie z. B. erhöhter Salzgehalt

und Starklicht, zu erhöhter Expression führen. Im Gegensatz jedoch zu einigen anderen MYB TFs, die einen Einfluss auf Gene des Anthocyanin-Biosyntheseweges ausüben, ist die Expression von *MYB112* nicht durch Stickstofflimitierung oder Kohlenstoffüberfluss kontrolliert, sondern wird durch erhöhten Salzgehalt sowie Starklicht stimuliert. Somit ist *MYB112* ein neuer Regulator, der eine Anthocyanin-Akkumulation unter abiotischen Stressbedingungen kontrolliert.
